TABLE OF CONTENTS	2
ABBREVIATIONS.....	4
SUMMARY	6
1 INTRODUCTION	7
1.1 LEGIONELLA PNEUMOPHILA.....	7
1.2 PATHOGENESIS OF <i>L. PNEUMOPHILA</i>	8
1.3 SECRETION SYSTEMS OF <i>L. PNEUMOPHILA</i>	9
1.3.0 TYPE IVA SECRETION SYSTEM (T4ASS)	10
1.3.1 TYPE IVB SECRETION SYSTEM (T4BSS)	10
1.4 RAB GTPASES	12
1.4.1 STRUCTURE OF RAB GTPASES.....	15
1.4.2 RAB ACTIVATION BY GEFS	17
1.5 HIJACKING OF RAB GTPASES BY <i>L. PNEUMOPHILA</i>	18
1.5.1 SidM/DRRA	18
1.5.2 SIDD, LEPB, AND LIDA	20
1.6 AIM OF THE WORK.....	20
2 MATERIALS AND METHODS	21
2.1 STANDARD MATERIALS	21
2.1.1 CHEMICALS, ENZYMES AND KITS	21
2.1.2 MOLECULAR WEIGHT STANDARDS AND KITS	21
2.1.3 CRYSTALLIZATION SCREENS	22
2.1.4 OLIGONUCLEOTIDES	22
2.1.5 PLASMIDS.....	23
2.1.6 RECOMBINANT PLASMIDS	23
2.1.7 BACTERIAL STRAINS.....	24
2.1.8 OTHER CHEMICALS	25
2.1.9 ANTIBIOTICS.....	25
2.2 MEDIA AND BUFFERS	25
2.3 MICROBIOLOGY	27
2.3.1 PREPARATION OF AGAR PLATES	27
2.3.2 LIQUID CULTURE.....	27
2.3.3 PREPARATION OF GLYCEROL STOCKS	27
2.4 MOLECULAR BIOLOGY.....	28
2.4.1 TRANSFORMATION OF COMPETENT BACTERIA.....	28
2.4.2 EXTRACTION OF PLASMID DNA	28
2.4.3 AGAROSE GEL ELECTROPHORESIS	29
2.4.4 SITE-DIRECTED MUTAGENESIS	29
2.4.5 RESTRICTION FREE CLONING	30
2.4.6 CO-EXPRESSION	30
2.5 PROTEIN PRODUCTION AND PURIFICATION	30
2.5.1 EXPRESSION TEST	30
2.5.2 RECOMBINANT PROTEIN PRODUCTION	31
2.5.3 PURIFICATION OF RAB1A AND SidM ₃₁₇₋₅₄₅	32
2.6 PROTEIN ANALYTICAL METHODS.....	33
2.6.1 CONCENTRATION OF PROTEINS.....	33
2.6.2 SDS-POLYACRYLAMIDE GEL ELECTROPHORESIS (SDS-PAGE).....	34
2.6.3 SURFACE PLASMON RESONANCE (SPR) SPECTROSCOPY.....	34
2.6.4 ISOTHERMAL TITRATION CALORIMETRY (ITC).....	34

2.7 CRYSTALLIZATION	35
2.8 X-RAY DATA COLLECTION	36
2.9 DATA PROCESSING AND STRUCTURE SOLUTION	36
3 RESULTS.....	37
3.1 HUMAN RAB1A, A SMALL GTPASE	37
3.1.1 PRODUCTION AND PURIFICATION OF RECOMBINANT RAB1A.....	37
3.1.2 C-TERMINAL DELETIONS OF RAB1A	38
3.1.3 PRODUCTION AND PURIFICATION OF STABLE RAB1A ₁₋₁₇₅	40
3.2 TYPE IVB EFFECTOR PROTEIN SIDM OF <i>LEGIONELLA PNEUMOPHILA</i>	41
3.2.1 PRODUCTION AND PURIFICATION OF SIDM ₃₁₇₋₅₄₅	41
3.2.3 CRYSTALLIZATION OF SIDM ₃₁₇₋₅₄₅	43
3.3 COMPLEX FORMATION OF SIDM ₃₁₇₋₅₄₅ /RAB1A ₁₋₁₇₅	44
3.3.1 PURIFICATION AND ANALYSIS OF SIDM ₃₁₇₋₅₄₅ /RAB1A ₁₋₁₇₅ COMPLEX.....	44
3.3.2 STABILITY OF SIDM ₃₁₇₋₅₄₅ /RAB1A ₁₋₁₇₅ COMPLEX.....	46
3.3.3 CO-EXPRESSION OF SIDM ₃₁₇₋₅₄₅ AND RAB1A ₁₋₁₇₅	47
3.4 SURFACE MUTAGENESIS OF RAB1A.....	48
3.4.1 RAB1A ^{K55S-K58S} AND RAB1A ^{E168A-K170S-K171A-R172S} VARIANTS	48
3.5 STRUCTURE OF SIDM ₃₁₇₋₅₄₅ /RAB1A ₁₋₁₇₅ COMPLEX.....	49
3.5.1 CRYSTALLIZATION OF SIDM ₃₁₇₋₅₄₅ /RAB1A ₁₋₁₇₅	49
3.5.2 DATA COLLECTION AND PROCESSING	50
3.5.3 STRUCTURE OF RAB1A ₁₋₁₇₅	51
3.5.3 STRUCTURE OF SIDM ₃₁₇₋₅₄₅	53
3.5.4 THE SIDM ₃₁₇₋₅₄₅ /RAB1A ₁₋₁₇₅ COMPLEX	54
3.5.5 INTERFACE OF THE SIDM ₃₁₇₋₅₄₅ /RAB1A ₁₋₁₇₅ COMPLEX.....	55
3.5.6 SWITCH I OF RAB1A ₁₋₁₇₅ CONTACTS A2, A5, A6 AND L _F OF SIDM ₃₁₇₋₅₄₅	56
3.5.7 SWITCH II CONTACTS OF RAB1A ₁₋₁₇₅ WITH SIDM ₃₁₇₋₅₄₅	57
3.5.8 P-LOOP AND OTHER CONTACTS OF RAB1A ₁₋₁₇₅ WITH SIDM ₃₁₇₋₅₄₅	58
3.6 ISOTHERMAL TITRATION CALORIMETRY (ITC) MEASUREMENTS	59
3.6.1 STATE A- RAB1A: GDP/SIDM ₃₁₇₋₅₄₅	60
3.6.2 STATE B: EDTA TREATMENT OF RAB1A/SIDM ₃₁₇₋₅₄₅	60
3.6.3 EFFECT OF RAB1A ^{K55A-K58S} VARIANT ON BINDING AFFINITY WITH SIDM	61
3.6.4 EFFECT OF RAB1 VARIANTS E35A, Y37A AND I41A ON BINDING TO SIDM	62
4 DISCUSSION.....	66
4.1 SIDM MANIPULATES RAB1A FUNCTION FOR <i>LEGIONELLA PNEUMOPHILA</i> SURVIVAL.....	66
4.2 SIDM INDUCES STRUCTURAL CHANGES ON RAB1A.....	66
4.2.1 STRUCTURAL MECHANISM OF NUCLEOTIDE EXCHANGE BY SIDM	67
4.3 SIDM AFFINITY FOR NUCLEOTIDE-FREE RAB1A IS HIGHER THAN FOR RAB1A:GDP	69
4.4 ROLE OF SWITCH I IN SIDM BINDING.....	70
4.4 COMPARISON OF SIDM/RAB1A WITH OTHER GEF/RAB COMPLEXES	70
5 CONCLUSIONS AND OUTLOOK	72
6 REFERENCES.....	74
ACKNOWLEDGEMENTS.....	80
CURRICULUM VITAE.....	82

Abbreviations

aa	Amino acid
Å	Ångström
AMP	Adenosine mono phosphate
AP	Alkaline phosphatase
APS	Ammonium persulphate
Bis-Tris	Bis(2-hydroxyethyl)amino-tris(hydroxymethyl)methan
CDP	Cytosine diphosphate
CV	Column volume
kDa	Kilo Dalton
<i>E. coli</i>	<i>Escherichia coli</i>
DMSO	Dimethyl sulfoxide
DOT	Defect in organelle trafficking
EDTA	Ethylenediaminetetraacetic acid
ER	Endoplasmic reticulum
GAP	GTPase activating protein
GDP	Guanosine di phosphate
GTP	Guanosine tri phosphate
GEF	Guanosine nucleotide exchange factor
GDI	Guanosine nucleotide dissociation Inhibitor
GDF	GDI displacement factor
GGTase	Geranylgeranyltransferase
LCV	Legionella containing vacuole
ICM	Intracellular multiplication
ITC	Isothermal titration calorimetry
IEC	Ion exchange chromatography
IMAC	Immobilized metal ion affinity chromatography
IPTG	Isopropyl-β-D-thiogalactoside
KPi	KH ₂ PO ₄ /K ₂ HPO ₄
MWCO	Molecular weight cut off

Mg ²⁺	Magnesium ions
Ni-NTA	Nickel-nitrilotriacetic acid-agarose
NMR	Nuclear magnetic resonance
OD ₆₀₀	Optical density at 600 nm
PAGE	Polyacrylamid gel electrophoresis
PCR	Polymerase chain reaction
PDB	Protein data bank
Pi	Inorganic phosphate
PI(4)P	Phosphatidylinositol 4-phosphatase
Rab	Ras-related proteins in brain
REP	Rab escort protein
SDS	Sodium dodecyl sulphate
SEC	Size exclusion chromatography
SNARE	Soluble N-ethylmaleimide-sensitive factor attachment
protein receptor	
SPR	Surface plasma resonance
TAE	Tris-acetate-EDTA
TBS	Tris buffered saline
TCA	Trichloroacetic acid
TEMED	N, N, N', N' – Tetramethyldiamin
Tris	Tris (hydroxymethyl) aminomethane
T4ASS	Type 4 A secretion system
T4BSS	Type 4 B secretion system
UTI	Urinary tract infection
WHO	World Health Organization
wt	Wild type

Amino acids are abbreviated using 1 or 3 letter code.

Latinisms are written in italic.

Summary

Rab1 is a small GTPase that regulates intracellular trafficking between the endocytosomal reticulum (ER) and the Golgi complex. In common with other GTPases, cytosolic Rab1 is normally kept in a GDP-bound, inactive state by a dedicated GDP-dissociation inhibitor (GDI). To activate Rab1, a GDI-displacement factor (GDF) is required to remove the GDI before a GTP exchange factor (GEF) can induce the release of GDP to allow for subsequent uptake of GTP and activation of Rab1. SidM is a type IV secretion system effector protein from *Legionella pneumophila* that has both GEF and GDF activity for Rab1GTPase. SidM recruits Rab1 to the *Legionella*-containing vacuole (LCV) as part of generating a specialized vacuole that resembles the host's rough endoplasmic reticulum. Within this vacuole *L. pneumophila* creates a replication niche allowing it to evade destruction by lysosomal fusion. To understand the SidM/Rab1 complex at the atomic level, the central domain of SidM₃₁₇₋₅₄₅ and Rab1A₁₋₁₇₅ were each purified and co-crystallized. Complex formation of SidM/Rab1 was analysed by size exclusion chromatography and isothermal calorimetry. The structure of the SidM/Rab1A complex was determined by X-ray crystallography revealing that the GEF domain of SidM is structurally distinct from known eukaryotic GEFs. The structure of the complex further revealed that SidM induces several conformational changes in Rab1A to facilitate GDP release. ITC experiments show that SidM has a higher affinity for unbound Rab1A compared to GDP-bound Rab1.

1 Introduction

Infectious diseases pose a significant threat to the global population. Recent reports from World Health Organization (WHO) have shown that infectious diseases account for more than 17 million deaths every year, the majority of which are due to bacterial infections (Millar et al., 2007). Bacterial infections result in acute to chronic illnesses especially in elderly people, children and immunocompromised patients. Common bacterial infections include pneumonia, diarrhea, urinary tract infections, ear and skin infections. Despite the availability of broad range of antibiotics, new bacterial strains are emerged that develop resistant to antibiotics. According to the latest reports from WHO, antibiotic resistant bacterial infections annually result in ~ 25 thousand deaths in the European Union alone (Reports from European Center For Disease Prevention And Control (ECDC, 2012). The associated medical costs and lost productivity are estimated to be around € 1.5 billion per year (Reports from European Center For Disease Prevention And Control (ECDC, 2012). Pathogenic bacteria have developed numerous strategies to escape the host immune system and survive inside host cells. Understanding the molecular mechanisms involving host-pathogen interactions is essential for the development of novel antimicrobial drugs and vaccines. In recent years, structural biology has become a powerful tool in the field of modern drug discovery. Use of structural biology methods such as X-ray crystallography and NMR will allow us to solve the three dimensional structures of biological proteins. This information can be used to design the therapeutic agents against the target proteins involved in the infectious diseases.

1.1 *Legionella pneumophila*

The genus *Legionella* is a Gram negative, aerobic, rod shaped motile bacterium that belong to the family of Legionellaceae (Edelstein 2007). To date more than 50 species of *Legionella* have been identified. Among them, *Legionella pneumophila* is a pathogenic bacterium that is universally found in freshwater environments such as ponds, lakes and also in association with amoeba and man-made aquatic environments like swimming pools, air-conditioning systems, cooling towers, water tanks, refrigerators, showers, respiratory devices etc.

In humans, *L. pneumophila* causes two forms of infections: Legionnaires' disease and Pontiac fever. Legionnaires' disease is a severe form of a pneumonia characterized by high fever, body pains, headache, nausea, shortness of breath and respiratory disorders that leads to chronic lung disease and can cause death in 5 to 30 % of the infected individuals (Edelstein 2007); (Tronel and Hartemann 2009; Cunha and Syed 2010) Legionnaires' disease was named after a massive outbreak of pneumonia affecting veterans at the American Legion convention in Philadelphia in 1976. Legionnaires' disease most commonly occurs in individuals suffering from chronic lung diseases, diabetes, AIDS/HIV, smokers, alcoholics and other immunocompromised individuals. The second manifestation of the disease, Pontiac fever, is a mild sickness. The symptoms include fever, dry cough, chilliness, muscle pains, and headaches but no pneumonia (Pancer and Stypulkowska-Misiurewicz 2003).

1.2 Pathogenesis of *L. pneumophila*

L. pneumophila is transmitted to humans through the inhalation of contaminated aerosols into the lungs. *L. pneumophila* has the ability to cause disease because it survives inside the host cells by escaping the bacteriocidal activities of the alveolar macrophages (Horwitz and Silverstein 1980) and resembles its lifecycle in amoebae. After uptake into macrophages, *L. pneumophila* resides inside the phagosome and survives inside the host cell by inhibiting the phagosome-lysosome fusion and the early endocytic pathway (Horwitz 1983). *L. pneumophila* utilizes a specialized system to manipulate the functions of host effector proteins like Rab1 and Arf1 involved in vesicle trafficking and thereby recruiting the vesicles derived from endoplasmic reticulum (ER) and ribosomes to the Legionella containing vacuole (LCV). Legionella makes use of the existing host machinery to form a specialized vacuole resembling the host rough endoplasmic reticulum (ER) studded with ribosomes (Derre and Isberg 2004). In the rough ER like vacuole, *L. pneumophila* replicates and eventually disrupts the vacuole membrane and lyses the host cell, which releases the bacterium into the extracellular environment for infecting neighbouring cells (Fig 1).

Figure 1: Life cycle of *L. pneumophila* after entry into a host cell. A bacterium of *L. pneumophila* is engulfed by macrophages by phagocytosis and resides in a phagosome. Endoplasmic reticulum derived vesicles are recruited to fuse with the phagosome to form ER-like vacuoles studded with ribosomes, where *L. pneumophila* establishes replication niche and subsequently lyses the host cell. Avirulent strains of *L. pneumophila* (or other bacteria) fail to recruit ER-derived vesicles and enter the endocytic pathway, killing bacteria by phagosome-lysosome fusion. (adopted from Jiannin and Feng, 2011)

1.3 Secretion Systems of *L. pneumophila*

The interaction of a pathogen with its host is critical for its infection process. For this purpose, bacteria utilize specialized secretion systems to deliver virulence proteins into the cytosol of the host cells. In Gram-negative bacteria such as *L. pneumophila*, effector proteins need to cross the inner and the outer bacterial membrane, and the host plasma membrane to reach their destined location. This is accomplished by secretion machineries exist in the Gram-negative bacteria. *L. pneumophila* contains four secretion systems namely, type I Lss, type II pilD-dependent Lsp, type IVA Lvh, type IVB Icm/Dot and type V secretion system respectively (Gerlach and Hensel 2007). Among these, a type IV

secretion system is important for the virulence of *L. pneumophila*. Type IV secretion system are subdivided into type IVA and type IVB.

1.3.0 Type IVA Secretion System (T4ASS)

The T4ASS, resembles the *Agrobacterium tumefaciens* T-DNA transfer system or Vir system and is named as *Legionella vir* homologues (LvH) system. Based on experimental evidences it was shown that *L. pneumophila* encodes 11 *lvh* genes (*lvhB2, B3, B4, B5, B6, B8, B9, B10, B11, D4*), and these are shown to be important in the virulence of *L. pneumophila* (Segal, Russo et al. 1999; Samrakandi, Ridenour et al. 2002).

1.3.1 Type IVB Secretion System (T4BSS)

The current work is mainly focused on effector proteins of T4BSS of *L. pneumophila*. Ralph Isberg and colleagues have identified approximately 20 *L. pneumophila* genes essential for intracellular replication and infection (Berger and Isberg 1994; Brand, Sadosky et al. 1994; Vogel, Andrews et al. 1998). Later these genes were collectively named *dot* (defect in organelle trafficking) or *icm* (intracellular multiplication). The *dot/icm* genes encode a T4BSS also known as Dot/Icm system, closely related to the Inc bacterial conjugative DNA-transfer systems (Segal and Shuman 1997; Vogel, Andrews et al. 1998). Several effector proteins of *L. pneumophila* are translocated into the cytosol of host cells using the Dot/Icm secretion system or T4BSS (Nagai, Kagan et al. 2002; Hubber and Roy 2010).

The Dot/Icm system is composed of mainly two subcomplex units, the outer membrane core transport complex and the coupling protein complex. The outer membrane core transport complex is composed of DotC, DotD, DotF, DotG and DotH proteins in which the inner membrane proteins DotF (interacts with secreted substrates) and DotG (homology to the VirB10 protein of the *A. tumefaciens*) form a complex and the C-terminal domain of DotG interacts with the outer membrane complex DotC, DotD and DotH. DotC and DotD are the outer membrane lipoproteins that recruit DotH an intrinsic periplasmic protein to the outer membrane, thereby forming a DotC-DotD-DotH-DotF-DotG outer membrane core transport complex [Fig 2 (Vincent, Friedman et al. 2006)]. However, more

detailed study is needed to get a better understanding of the T4BSS or Icm/Dot secretion system of *L. pneumophila*.

Figure 2: Components of type IVB secretion system (T4BSS) of *L. pneumophila*. The core transport complex that links the inner and outer membranes is composed of DotC, DotD, DotF, DotG and DotH [(Dot-Defect in organelle trafficking). The inner membrane proteins DotF and DotG interact and form a subcomplex with the outer membrane lipoproteins DotC, DotD and DotH. The coupling protein complex is composed of DotL (recruits IcmSW substrates to the transport complex), DotM, DotN, IcmS and IcmW [adapted from (van Schaik, Chen et al. 2013)].

To date biochemical, genetic and bioinformatics analyses have identified ~250 Dot/Icm substrate proteins (Nagai, Kagan et al. 2002; Conover, Derre et al. 2003; Luo and Isberg 2004; Campodonico, Chesnel et al. 2005; de Felipe, Pampou et al. 2005; Ninio, Zuckman-Cholon et al. 2005; Shohdy, Efe et al. 2005; Laguna, Creasey et al. 2006; Machner and Isberg 2006; Murata, Delprato et al. 2006; VanRheenen, Luo et al. 2006; Zusman, Aloni et al. 2007; Altman and Segal 2008; Kubori, Hyakutake et al. 2008; Zhu, Hu et al. 2010). The biochemical function of some substrates was identified while others remain to be studied. Some have C-terminal translocation signals for the substrate identification (Details are given in section 1.5).

1.4 Rab GTPases

Eukaryotic cells consist of several distinct intracellular compartments, which require well defined regulation of transport of vesicles to their designated location (Jordens, Marsman et al. 2005). The process of membrane trafficking occurs in a series of steps, where the donor membranes protrude to form vesicles. Rab GTPases deliver these vesicles to the acceptor membranes via microtubules or actins by recruiting motor adaptor proteins. In the next step, vesicles fuse to their target membrane with the help of rod-shaped tethering factors and SNAREs (Soluble N-ethylmaleimide-sensitive factor attachment protein receptor) by a process called as tethering (Stenmark 2009). Cell biology studies on membrane trafficking have shown that Rab (Ras-related proteins in brain) GTPases are involved in regulating the membrane trafficking events by binding to the diverse group of effector proteins, motor proteins and tethering complexes (Segev 2001; de Renzis, Sonnichsen et al. 2002; Hammer and Wu 2002; Novick, Medkova et al. 2006; Cai, Reinisch et al. 2007).

Rab proteins belong to the Ras super family of small GTPases (Wennerberg, Rossman et al. 2005). To date more than 60 Rab genes have been identified in the human genome (Pereira-Leal and Seabra 2000; Bock, Matern et al. 2001; Pereira-Leal, Hume et al. 2001). Rab proteins are located on the endoplasmic reticulum, Golgi apparatus, endosomes, lysosomes, nucleus, plasma membrane and mitochondria (Schwartz, Cao et al. 2007). Rab GTPases are involved in membrane trafficking, signalling events, regulation of cell proliferation and differentiation (Bucci and Chiariello 2006; Schwartz, Cao et al. 2007).

Rab GTPases operate in two conformations, one is guanosinediphosphate (GDP)-bound 'inactive' state and the other one is guanosine triphosphate (GTP)-bound 'active state' (Stenmark, Valencia et al. 1994; Zerial and McBride 2001). Rabs do not exhibit high nucleotide exchange and hydrolysis activities, so the exchange of GDP to GTP or vice versa is accomplished by specialized proteins called guanine nucleotide exchange factors (GEFs) and GTPase-activating proteins (GAPs). In the cytosol, GDP Rab is solubilized by being in complex with guanine nucleotide dissociation inhibitor (GDI). For the membrane insertion of C-terminus of Rab, GDI need to be displaced from Rab:GDP and this is accomplished by GDI displacement factor (GDF) (Pfeffer and Aivazian 2004). Once

Rab:GDP is targeted to the membrane by GDI, GEF activates Rab by catalyzing the exchange of GDP for GTP. The GTP-bound active Rab interact with their downstream effector proteins to regulate several cellular functions such as membrane trafficking, signalling events, regulation of cell proliferation and differentiation. Eventually, the GTP-bound 'active' Rab is converted back to the GDP-bound 'inactive' by the GAP, which

Figure 3: Rab GTPase Cycle. Rab GTPases operate between GDP and GTP-bound forms. Exchange of GDP for GTP is catalyzed by the GDP/GTP exchange factor (GEF). The GTP-bound 'active' form interacts with its effector proteins and is converted back to the GDP-bound 'inactive' form by the GTPase activating protein (GAP), which promotes hydrolysis of GTP and releases an inorganic phosphate (Pi). Rab escort protein (REP) presents the newly synthesized GDP-bound Rab to a prenylating enzyme Rab geranylgeranyltransferase (RabGGTase), which geranylgeranylates one or two carboxy-terminal Cys residues of the Rab. The geranylgeranylated, GDP-bound Rab is further recognized by Rab GDP dissociation inhibitor (GDI). The GDI displacement factor (GDF), releases GDI from the Rab-GDI complex and recruits GDP-bound Rab to the target membrane [adapted from (Stenmark and Olkkonen 2001)].

effector proteins to regulate several cellular functions such as membrane trafficking, signalling events, regulation of cell proliferation and differentiation. Eventually, the GTP-bound 'active' Rab is converted back to the GDP-bound 'inactive' by the GAP, which facilitates the hydrolysis of GTP by releasing inorganic phosphate (Pi). The Rab GTPase cycle is circumvented by the extraction of Rab:GDP from the target membrane to the cytoplasm by GDI [(Fig 3) (Somsel Rodman and Wandinger-Ness 2000; Esters, Alexandrov et al. 2001; Gurkan, Lapp et al. 2005)].

Rab GTPases are targeted to specific membranes by a post-translational modification known as prenylation, where 20-carbon geranylgeranyl group is attached to one or two carboxy-terminal Cys residues of the Rab (Andres, Seabra et al. 1993). The prenylation of Rab GTPases is carried out by two conserved paralogs, Rab escort protein (REP) and Rab-GDI (Alory and Balch 2001; Pereira-Leal, Hume et al. 2001). REP is responsible for presenting the newly synthesized Rab proteins to the prenylating enzyme Rab geranylgeranyltransferase (RabGGTase) for geranyl-geranylation process and then delivers Rab proteins to target membranes. Rab GDI is important for Rab recycling by extracting inactive Rab proteins from membranes after GTP hydrolysis. The GDF, releases GDI from the Rab-GDI complex and recruits GDP-bound Rab to the target membrane (Ullrich, Stenmark et al. 1993; Sivars, Aivazian et al. 2003). REP binds either prenylated or unprenylated GDP bound Rab proteins with high affinity, whereas GDI binds prenylated Rab with higher affinity than to unprenylated Rab proteins (Plutner, Cox et al. 1991; Wu, Tan et al. 2007).

1.4.1 Structure of Rab GTPases

Figure 4: Crystal structures of Rab GTPases in GDP-bound, inactive and GTP-bound active conformation. (A) Structure of Rab1A bound to GDP and Mg^{2+} showing switch II in disordered conformation (Left). Structure of Ypt1:Guanosine 5'-[β , γ -imido] triphosphate (GppNHP: non- hydrolyzable analogue of GTP) showing switch II adopted ordered confirmation (Right). (B) Several Rab GTPase structures in active and inactive bound conformations are aligned showing structural differences (Left: GDP bound inactive conformations, Right: GTP bound active conformations). Structural elements; P-loop coloured in magenta, switch I in blue, switch II in red and interswitch regions in orange, GDP and Mg^{2+} are shown in stick and sphere representation (Details of the above structures are given in Table 1).

Table 1: Structures of Rab GTPases represented in Figure 4 are summarized below

Protein	Ligand	PDB ID
Rab/GDP (Fig 5)		
Rab1A	GDP	2FOL
Rab2A	GDP	1Z0A
Rab3B	GDP	3DZ8
Rab3D	GDP	2GF9
Rab4B	GDP	2O52

Ypt1/GDI	GDP	1UKV

Rab proteins exhibit common structural features of Ras-related GTPases, comprising of a six-stranded- β sheet, with five parallel strands and one antiparallel strand, enclosed by five α - helices (Vetter and Wittinghofer 2001). Crystallographic analysis of various Rabs in the GDP- and GTP-bound states shows that the protein adopts two different conformations and these conformational changes are confined to two regions namely switch I and switch II (Fig 4 A&B). Magnesium ions (Mg^{2+}) are important for the high affinity binding of nucleotide to the Rab GTPases. Guanine nucleotides interact with residues from five G-motifs that are highly conserved in all GTPases. The G1 motif also commonly known as P-loop (phosphate binding loop) consists of consensus sequence GxxxxGKS/T that binds to phosphate and Ser/Thr is coordinated by the Mg^{2+} . The G2 motif in the switch I region has threonine residue that interacts with γ -phosphate and the Mg^{2+} ion. The G3 motif in the switch II region has a conserved DxxGQ sequence where the aspartate establishes water mediated ionic interaction with Mg^{2+} , the glycine interacts with the γ -phosphate and the glutamine acts as a catalytic residue for the GTP hydrolysis. The residues in the G4 and G5 motifs interact with the guanine base and also distinguish from other nucleotides (Khosravi-Far, Lutz et al. 1991; Vetter and Wittinghofer 2001).

Several crystal structures are available for RabGTPases in the GDP bound inactive state and GTP bound active state (Table 1). In the GDP bound inactive state, the switch regions are largely disordered or adopts ordered conformations based on the crystal packing, where in the GTP-bound active state, the switch regions adopts ordered conformation [(Eathiraj, Pan et al. 2005) (Fig 4B)].

1.4.2 Rab activation by GEFs

As explained in the previous section, activation of Rab GTPases is regulated by the switch between GDP bound inactive state and GTP bound active state. Rab GTPases form multiple contacts with guanosine nucleotides involving G motifs and Mg^{2+} . The affinity of GDP to Rab family is high and hence the release of GDP from Rab GTPases occurs at a

very slow rate by itself and this process is accelerated by GEF. GEFs establish competition with nucleotides for binding to GTPases. To date only few Rab GEFs have been identified because of their diversity in the sequence, structure, size and complexity (Lee, Mishra et al. 2009). Structures of five Rab-GEFs in complex with their specific Rab GTPases have been determined. They are MSS4-Rab8, Sec2p-Sec4p, Rabex-5-Rab21, TRAPP1-Ypt1p and DENN1B-S-Rab35. These structures will be explained in detail in the discussion chapter. Briefly, based on the available structural information about GEF-GTPase complex, it was explained that GEFs induces structural changes on Rab GTPases, especially on the nucleotide binding sites of switch I and switch II regions. These structural rearrangements lead to the wide opening of the nucleotide binding pocket and release of Mg^{2+} . This results in reducing the binding affinity between nucleotide and Rab GTPases.

1.5 Hijacking of Rab GTPases by *L. pneumophila*

L. pneumophila able to survive inside the host cell by modulating several functions of host proteins by delivering large set of effector proteins in to the host cytosol via T4BSS also known as Dot/Icm. Some of the Dot/Icm effector proteins namely SidM/DrrA, SidD and LepB mimic the function of host GEF, GAP and GDF proteins that are involved in the activation and inactivation of Rab1 GTPase.

1.5.1 SidM/DrrA

Figure 5: Domain organization of SidM/DrrA. N-terminus harbouring AMPllyation domain, central part with GEF domain and C-terminal P4M domain

SidM, a Dot/Icm effector protein of *L. pneumophila* recruits Rab1 onto the LCV. Rab1 is a small GTPase involved in the regulation of vesicle trafficking between ER and Golgi complex. SidM also named as DrrA contains 647 amino acid residues comprises of three domains: a C-terminal novel phosphatidylinositol 4-phosphatase (PI(4)P)-binding domain,

a central domain exhibiting GEF and GDF activity for Rab1 and an N-terminal domain displaying adenylyl transferase (AMPylation) activity (Fig 5). Inside the host cell, SidM is anchored to the LCV by the action of PI4P domain that binds with high affinity to PI4P located on the vacuolar membrane (Brombacher, Urwyler et al. 2009; Schoebel, Blankenfeldt et al. 2010; Zhu, Hu et al. 2010). The central GEF/GDF domain of SidM enables the recruitment of Rab1 to the LCV by detaching GDI from Rab:GDP:GDI complex and activates Rab by catalyzing the GDP/GTP exchange (Machner and Isberg 2006; Murata, Delprato et al. 2006; Ingmundson, Delprato et al. 2007). The N-terminal domain with adenylation activity catalyses transfer of adenosine mono phosphate (AMP) to a conserved Tyr 77 in the switch II region of Rab1:GTP. This modification inhibits the hydrolysis of GTP to GDP, maintaining Rab1 in the active form (Muller, Peters et al. 2010). By the action of SidM, Rab1 efficiently remodels the LCV into an ER- like derived vesicle, where *L. pneumophila* replicates and escapes the lysosomal fusion. This is how the multi functional SidM/DrrA is important for the pathogenicity of *L. pneumophila*.

Figure 6: Regulation of Rab1 activity cycle by Dot/Icm effector proteins of *L. pneumophila* on the LCV. *L. pneumophila* secretes effector proteins into the host cytosol via T4BSS or Dot/Icm. SidM is anchored to the LCV by PI(4)P binding to recruit GDP-bound Rab1 to the LCV by detaching it from the Rab1-GDI complex and later activates Rab1 by catalyzing the exchange of GDP for GTP. SidM then

AMPylation (adding AMP) GTP-bound Rab1 at Tyr 77 to retain Rab1 in its active form, which is not accessible to GAPs. SidD deAMPylation (remove AMP) Rab1, which makes it accessible for inactivation by LepB mediated GTP hydrolysis. Finally, inactive GDP-bound Rab is accessible for GDI to remove it from the LCV membrane [Adopted from (Neunuebel and Machner 2012)] .

1.5.2 SidD, LepB, and LidA

SidD is another Dot/Icm effector protein consisting of 507 amino acids, deAMPylation Rab1 by harbouring protein phosphatase-like catalytic domain (Neunuebel, Chen et al. 2011; Tan and Luo 2011). SidD makes Rab1 accessible for inactivation by LepB. LepB also a T4B effector protein exhibits GAP activity and inactivates Rab1 by promoting hydrolysis of GTP to GDP and removes Rab1 from the LCV (Ingmundson, Delprato et al. 2007). The inactive GDP-bound Rab1 is extracted from the membrane by the action of GDI. LidA, the other T4B effector protein binds to various Rabs regardless with the bound nucleotide form, but shows higher affinity towards Rab1-GTP (Conover, Derre et al. 2003; Machner and Isberg 2006). LidA is also thought to involve in assisting SidM for the recruitment of Rab1 onto the LCV and in maintaining bacterial cell integrity (Machner and Isberg 2006; De Buck, Anne et al. 2007). The mechanism of its function is not clearly known.

The combined action of SidM/DrrA catalysed nucleotide exchange and AMPylation, SidD catalysed deAMPylation and LepB-catalysed GTP hydrolysis of Rab1A explains the unique mechanism of *L. pneumophila* in regulating the Rab1 cycle (Fig 6).

1.6 Aim of the work

The T4B or Icm/Dot effector protein SidM of *L. pneumophila* is shown to have GEF and GDF activity towards Rab1 GTPase. One aim of this work is to produce and purify SidM₃₁₇₋₅₄₅ and Rab1a to analyse the stable complex formation of two proteins by size exclusion chromatography (SEC) and Isothermal titration calorimetry (ITC). The second aim is to solve the crystal structure of SidM₃₁₇₋₅₄₅ and SidM₃₁₇₋₅₄₅/Rab1a complex by X-ray crystallography to elucidate the mode of interaction between two proteins.

2 Materials and Methods

2.1 Standard Materials

If not mentioned otherwise, all chemicals and reagents used were purchased from Qiagen, Sigma Aldrich, Fluka, Invitrogen, GE Healthcare, Millipore, Hampton Research, Roche, Merck, Stratagene, Pall and Inqaba Biotech.

2.1.1 Chemicals, Enzymes and Kits

Table 1: Enzymes

Enzyme	Source
Benzonase	Structural Biology Group, HZI
DNaseI	Roche
PreScission Protease	Structural Biology Group, HZI
TEV protease	Structural Biology Group, HZI
Pfu DNA polymerase	Invitrogen
DpnI	Fermentas
T4 DNA Ligase	New England Biolabs

SOC-Medium	Tryptone	20 g/L
	Yeast extract	5 g/L
	NaCl	10 mM
	KCl	2.5 mM
	MgCl ₂	10 mM
	Glucose	20 mM

Table 12: Solutions and buffers

Buffers/Solutions	Composition
Lysis buffer	1 x PBS (Phosphate Buffered Saline) pH 7.0, 2.5 mM MgCl ₂ , Complete EDTA-free Protease Inhibitor Cocktail Tablet, 5 mM β-mercaptoethanol and DNaseI (10 µg/mL)
PreScission protease cleavage buffer	10 mM Tris/HCl pH 7.0, 150 mM NaCl, 5 mM β-mercaptoethanol
Ni-NTA binding buffer	1 x PBS pH 7.0, 10 mM imidazole, 5 mM β-mercaptoethanol,
Ni-NTA elution buffer	1x PBS pH 7.0, 250 mM imidazole, 5 mM β-mercaptoethanol
TEV cleavage buffer	50 mM Tris/HCl pH 7.5, 150 mM NaCl, 20 mM EDTA, 5 mM β-mercaptoethanol
Anion exchange buffer A1 (Rab1A)	20 mM Tris/HCl pH 7.0, 10 mM NaCl, 5 mM β-mercaptoethanol
Anion exchange buffer B1 (Rab1A)	Buffer A1 (Rab1A) + 1 M NaCl
Cation exchange buffer A1 (SidM)	20 mM Tris/HCl pH 8.0, 10 mM NaCl, 5 mM β-mercaptoethanol
Cation exchange buffer B1(SidM)	Buffer A1 (SidM) + 1M NaCl
Anion exchange buffer A2 (Rab1A/SidM)	20 mM Tris/HCl pH 7.0, 10 mM NaCl, 5 mM β-mercaptoethanol
Anion exchange buffer B2 (Rab1A/SidM)	Buffer A1 (Rab1A/SidM) + 1M NaCl
Gel filtration buffer (Rab1A/SidM)	50 mM Tris/HCl pH 7.5, 150 mM NaCl, 5 mM β-mercaptoethanol
ITC buffer	50 mM HEPES pH 8.0, 50 mM NaCl
TAE buffer	40 mM Tris/HCl pH 7.5, 20 mM sodium acetate, 1 mM EDTA. Adjust pH to 8.2 with acetic acid
10 x DNA loading buffer	70 % (w/v) sucrose, 0.25 % (w/v) bromphenol blue, 0.1 M EDTA
SDS-PAGE lower buffer (4 x)	1.5 M Tris/HCl pH 8.8
SDS-PAGE upper buffer (4 x)	0.5 M Tris/HCl pH 6.8, 0.4 % (w/v) SDS
SDS-PAGE running buffer	25 mM Tris/HCl, 192 mM glycine, 0.1 % (w/v) SDS
SDS-PAGE sample buffer (8 x)	16 mL 10 % SDS, 4 mL glycerol, 2.2 mL Tris/HCl, pH 6.8, 800 µL β-mercaptoethanol,

	1 spatula tip bromophenol blue
SDS-PAGE separating gel (15 %)	15 mL acrylamide/bisacrylamide 30 % (w/v)/ 0.8 % (w/v), 7.6 mL 1.5 M Tris/HCl, pH 6.8, 300 µL 10 % (w/v) SDS, 10 mL ddH ₂ O, 40 µL TEMED, 100 µL 25 % (w/v) APS
SDS-PAGE stacking gel (5 %)	1.5 mL acrylamide/bisacrylamide 30 % (w/v)/0.8 % (w/v), 2.5 mL 0.5 M Tris/HCl, pH 6.8, 5.9 mL ddH ₂ O, 15 µL TEMED, 25 µL 25 % (w/v) APS
SDS-PAGE Staining solution	0.25 % (w/v) Coomassie Brilliant Blue R-250, 30 % (v/v) ethanol, 10 % (v/v) acetic acid
SDS-PAGE destaining solution	40 % (v/v) ethanol, 10 % (v/v) acetic acid

2.3 Microbiology

2.3.1 Preparation of Agar Plates

Agar plates were used to culture bacteria on solid medium. Agar plates were prepared following standard procedure: 15 g agar was added to 1 L LB-medium. The solution was sterilized by autoclaving and allowed to cool to ~55 °C. Required antibiotics were added and 25 mL of agar was poured into each Petri dish). Bacteria were plated on LB agar plates with respective antibiotics on a sterile clean bench with sterile beads or spreading inoculation loops.

2.3.2 Liquid culture

Bacteria were grown in liquid medium using Erlenmeyer flasks for proper aeration and agitation. The flasks containing inoculated liquid medium with appropriate antibiotics were incubated at 37 °C with a rotation speed of 160-180 rpm overnight. Liquid bacterial cultures were made for precultures, protein production, preparation of DNA and glycerol stocks.

2.3.3 Preparation of Glycerol Stocks

Glycerol stocks were prepared for long-term storage of the bacterial cells containing plasmid of interest. 5 mL LB-medium was inoculated with bacteria harboring a plasmid of

interest. Appropriate antibiotics were added and incubated overnight at 37 °C and a rotation speed of 160-180 rpm. 900 µL of this culture was mixed with 100 µL of sterile 80 % glycerol (cryoprotectant) in a 1 mL cryo-vial and then stored at -80 °C.

2.4 Molecular Biology

2.4.1 Transformation of Competent Bacteria

Competent bacterial cells were transformed with plasmid DNA for plasmid amplification and recombinant gene expression. Positive clones were selected by plating the transformation mixture on LB agar plates containing antibiotics corresponding to plasmid resistance genes.

Heat shock transformation

Plasmid DNA (1-2 µL) obtained from ligation reactions was added to 50 µL of competent cells that were thawed on ice. The cells were incubated on ice for 30 minutes and treated with heat shock for 45 s at 42 °C, followed by fast cooling on ice for 2 min. 800 µL of SOC or LB medium were added to the cells and shaken at 37 °C for 1 h on a thermo-mixer. The transformation mixture was plated on LB agar plates containing appropriate antibiotics and incubated at 37 °C overnight.

Electroporation

Plasmid DNA (1-2 µL) was transferred in to a pre-cooled electroporation cuvette, followed by the addition of 50 µL competent cells (thawed on ice). The cuvette was dried and an electric pulse of 2.5 kV, 200 Ω and 125 µF was applied to the cells using Gene Pulser electroporation equipment (Bio-Rad). 800 µL of SOC or LB-medium was added immediately to the cells and incubated at 37 °C for 1h on a thermo-mixer. The transformation mixture was plated on LB agar plates using appropriate antibiotics.

2.4.2 Extraction of Plasmid DNA

Freshly transformed *E. coli* XL1 blue cells were transferred to 5 mL of LB medium with appropriate antibiotics and allowed to grow at 37 °C in a shaking incubator overnight. Plasmid DNA was isolated using QIAGEN mini prep kit. Purification of the plasmid DNA was performed according to the manufacturer's instructions. The yield of DNA was measured by detecting the absorption at 260 nm (A_{260}) using a Nanodrop ND-1000 spectrophotometer (peqLab, Erlangen, Germany)

2.4.3 Agarose gel electrophoresis

Agarose gel electrophoresis is a common method for analyzing DNA samples. In this method, DNA migrates through the agarose matrix when an electric current is applied. Phosphate groups on the DNA impart a negative charge to the molecule and migrate towards a positively charged pole. 1 % agarose gel was prepared by dissolving 0.5 g of agarose in 50 mL of TAE buffer, brought to boil in a microwave for 1min. The agarose solution was allowed to cool down to ~60 °C and SYBR Green was added to visualize the DNA samples. DNA samples were mixed with 10 % loading buffer (10 x) and loaded into the sample wells. Gels were run at 5 V/cm for 60 min and later visualized under a UV illuminator.

2.4.4 Site-directed mutagenesis

Site-directed mutagenesis is a technique to replace, delete or insert a number of nucleotides into a target DNA by PCR using appropriately designed primers. Mutagenesis reactions were performed using the Quick Change Kit (QIAGEN). The reaction products were treated with DpnI restriction enzyme for 1 h at 37 °C to digest the methylated template DNA. The DpnI digested products were transformed into XL1 blue competent cells. The transformation mixture was plated on LB agar plates with appropriate antibiotics. Positive clones were analyzed by DNA sequencing. Given below are the parameters for PCR

Table 13: Reaction mixture

Reaction components	Volume (μL)	Concentration
10x PFU Ultra II buffer	10.0	1 x
Template DNA	1.0	50 ng
Mutagenesis forward primer	1.25	10 pmol/μL
Mutagenesis reverse primer	1.25	10 pmol/μL
dNTP's mix	1.0	10 μM
Pfu Ultra HS II DNA-polymerase (Stratagene)	1.0	1 U
Total volume	50.00	

Table 14: Mutagenesis reaction programme

Step1	Initial denaturation	95 °C	1 min
Step2	Denaturation	95 °C	50 s
Step3	Annealing	55°C	50 s
Step4	Elongation	68 °C	7 min

Step5	Final elongation	68 °C	9 min
Repeat steps 2-4 18 times			

2.4.5 Restriction free cloning

Restriction free (RF) cloning is a simple method compared to conventional cloning whereby a gene of interest can be inserted at any desired location into a vector, independent of restriction sites, ligation or any modifications in both vector and gene. In this work, the gene *sidM* was cloned into pETM-30 vector using this method. A set of primers 50 bases in length were designed harboring complementary sequences to both *sidM* and to the vector. The forward primer had an overlap of 24 bases with the vector sequence complementary to the 5'-end of the target site of insertion, followed by a start codon and 20-25 bases of the 5'-end of *sidM*. The reverse primer of 24 bases was complementary to the 3' end of the vector at the target site of insertion (Fusinita et al., 2006). The reaction mixture containing the template, primers, dNTP's, polymerase and buffer was amplified by PCR and the resultant products were analyzed by agarose gel electrophoresis. The double-stranded, blunt-ended PCR product was used as a set of primers for a second PCR to insert the amplified gene into the desired vector. The final product was digested with DpnI for 1 h at 37 °C and transformed into XL1 blue cells. Positive clones were analyzed by DNA sequencing.

2.4.6 Co-expression

The vectors pGEX-6P-1_Rab1A₁₋₂₁₀ and pETM30_SidM₃₁₇₋₅₄₅ were co-transformed into *E. coli* BL21-CodonPlus cells (Stratagene) for co-expression of the two respective genes. The transformation mixture was plated on LB-agar plates containing ampicillin, kanamycin and chloramphenicol. Positive clones were confirmed by protein expression test.

2.5 Protein Production and Purification

2.5.1 Expression Test

To optimize the expression of a target recombinant gene (Table 8), various parameters such as temperature, isopropyl- β -D-1-thiogalacto pyranoside (IPTG) concentration and induction time were tested. The recombinant plasmids harboring a gene of interest (Table 8) were transformed into *E. coli* BL21 and/or Rosetta 2 expression cells. In each case, a single colony was picked from the LB agar plate and transferred to 5 mL of LB-medium

with appropriate antibiotics and grown overnight at 37 °C in a shaking incubator. The overnight pre-culture cells were transferred into 50 mL of LB-medium with appropriate antibiotics and incubated at 37 °C, 180 rpm until cell density reached an OD₆₀₀ value of 0.5-0.8. Expression of the target genes was induced with 0.1 mM IPTG. Samples were taken before induction and every 2 h after induction i.e. at 2, 4, 6 h and overnight. Samples were then centrifuged for 1 min at 13000 rpm. The bacterial pellet containing total cell extract was resuspended in 100 µL Bug-Buster reagent and incubated at room temperature for 20 min, followed by centrifugation for 20 min at 13000 rpm. The supernatant containing all soluble proteins was collected for the analysis of the target recombinant protein production. The pellet was resuspended in an equal volume of 8 M urea. Samples of the soluble and insoluble fractions were analyzed by SDS-PAGE.

2.5.2 Recombinant Protein Production

In this work pGEX-6P-1_SidM₃₁₇₋₅₄₅, pGEX-6P-1_Rab1A₁₋₂₁₀ and pGEX-6P-1_Rab1A plasmid constructs were expressed in *E. coli*. BL21, BL21-CodonPlus and Rosetta 2. Cells harboring the respective recombinant plasmids were thawed from glycerol stocks and grown in 50 mL LB-medium containing appropriate antibiotics at 37 °C and 180 rpm overnight. The resulting 0.1 OD₆₀₀ pre-culture was transferred to 2 L of LB-medium with appropriate antibiotics. The cells were permitted to grow at 37 °C and 180 rpm until they reached an OD₆₀₀ of 0.5-0.8. The expression of the gene of interest was induced by 0.1 mM IPTG and the cultures were incubated at 18, 25, 37 °C, 180 rpm respectively. After overnight incubation, cells were harvested by centrifugation: 15 min, 4 °C, 6000 rpm. The supernatant was discarded and the cell pellet resuspended in 15 mL lysis buffer per 1 L culture at 4 °C. The cell suspension was passed through a homogenizer (Constant systems 20 kPa, 4 °C, 2-3 runs for efficient cell lysis. After cell lysis DNase I was added to degrade DNA and reduce sample viscosity. The lysate was centrifuged for 1 h at 4 °C and 16000 rpm to separate the soluble protein fraction from cell debris and inclusion bodies. Soluble and insoluble fraction samples were collected to analyze the target protein production by SDS-PAGE.

2.5.3 Purification of Rab1A and SidM₃₁₇₋₅₄₅

Affinity chromatography

Affinity chromatography is based on the principle of strong and specific binding of affinity tag fused to the N- or C-terminus of the target protein to an immobilized matrix. In this work, the central domain of SidM₃₁₇₋₅₄₅ was produced as a fusion protein with an N-terminal glutathione S-transferase (GST) tag whereas Rab1A₁₋₂₁₀ and variants were produced with an N-terminal GST and a C-terminal His₆-tag.

Glutathione/Glutathione-S-Transferase Affinity Chromatography

This method is based on the high affinity of GST for its substrate glutathione. GST is used as an affinity tag fused to a target protein. In this work, both SidM and Rab1A were purified by producing N-terminal GST fusion proteins. After cell lysis, the soluble fraction was added to the PBS pre-equilibrated glutathione sepharose (GS) beads and incubated at 4 °C for 1 h with agitation to allow the target protein to bind. The flow through was collected to check for possible unbound fusion protein. Loaded GS beads were washed 4 times (50 mL) with PBS buffer to remove unbound and non-specifically bound proteins and further washed 3 times (30 mL) with PreScission Protease Cleavage Buffer. The GST-SidM and -Rab1A fusion proteins were proteolytically cleaved by adding PreScission protease and incubating the GS at 4 °C overnight. SidM and Rab1A proteins were eluted from the GS beads using 60 mL PreScission Protease Cleavage Buffer.

Ni-NTA affinity chromatography

Ni-NTA agarose beads are used for the purification of recombinant proteins with so-called His₆-tags. Histidine residues of the His₆-tag bind to the immobilized nickel ions with high specificity and affinity. In this study, Rab1A₁₋₂₁₀ and variants thereof were produced as fusion proteins bearing a C-terminal His₆-tag. Elution fractions of Rab1A from glutathione affinity chromatography purification were pooled and coupled to the pre-equilibrated (PBS buffer) Ni-NTA agarose beads at 4 °C for 1 h. The flow-through was collected to check for the presence of unbound fusion protein followed by extensive washing of beads with PBS. The beads harboring the His₆-tagged target protein were further washed with 10 column volumes (CV) wash buffer containing 10 mM imidazole (Table 12) to remove impurities. The pure His₆-tag protein was eluted with 5 CV of elution buffer containing 250 mM imidazole. The efficiency of protein fusion binding, yield of fusion protein and purity were analyzed by SDS PAGE.

Ion exchange chromatography

Ion exchange chromatography separates protein samples based on their electrostatic properties. In cation exchange chromatography, positively charged protein molecules bind to a negatively charged resin and *vice versa* in anion ion exchange chromatography. Before applying the sample, the column was washed with buffer containing a high NaCl concentration to displace all other charged species. Washing with a low ionic strength buffer then removes all unbound Na^+ and Cl^- ions. After binding and washing, the bound proteins were eluted using a linear NaCl gradient. The binding of the protein to the resin depends on the pH of the solvent.

In this work, Rab1A₁₋₂₁₀ and Rab1A₁₋₂₁₀/SidM₃₁₇₋₅₄₅ complex were purified by anion exchange chromatography (MonoQ HR 10/100 GL, GE Healthcare) and SidM₃₁₇₋₅₄₅ by cation exchange chromatography (MonoS HR 10/100GL, GE Healthcare). The peak fractions were collected and analyzed on the SDS-PAGE for the target protein.

Size exclusion chromatography

Size exclusion chromatography (SEC) is also referred to as gel permeation chromatography or gel filtration. It separates proteins based on their molecular size (hydrodynamic volume). Proteins larger than the pores size of the resin material unable to enter the porous particles will pass through the space in between the beads and will elute first. Smaller molecules will be retained in the porous particles and elute at slower rate. In this work, affinity purified Rab1A₁₋₂₁₀ and SidM₃₁₇₋₅₄₅ were mixed and subjected to SEC. The peak fractions were collected and analyzed on the SDS-PAGE to analyze the formation of Rab1A₁₋₂₁₀ /SidM₃₁₇₋₅₄₅ complex. All the SEC experiments were conducted on ÄKTA purifiers with HiLoad Superdex 75 and 200 10/30, 16/60 and 26/60 columns.

2.6 Protein Analytical Methods

2.6.1 Concentration of Proteins

Protein samples were concentrated for SEC, Isothermal Titration Calorimetry (ITC) and crystallization experiments by ultracentrifugation using Vivaspin 2, 6 and 20 concentrators with desired molecular weight cut-offs. The molecular weight cut-off of the concentrators was selected at least 10 kDa smaller than the protein. The concentration of purified proteins were measured by measuring the absorption at 280 nm (A_{280}) using a Nanodrop ND-1000 spectrophotometer (peqLab, Erlangen, Germany)

2.6.2 SDS-Polyacrylamide Gel Electrophoresis (SDS-PAGE)

Protein samples were analyzed by sodium dodecyl sulfate (SDS) polyacrylamide gel electrophoresis (PAGE). This technique separates proteins based on their molecular weight. SDS is a strong anionic detergent that binds non-covalently to proteins disrupting their native structure. SDS treated proteins are negatively charged and migrates towards a positively charged anode in an electric field. Protein samples were mixed with 8x sample buffer (10 μ L protein +2 μ L sample buffer). Samples were heated at 95 °C for 5 min to denature the protein. The protein samples were loaded onto the gel and run at constant 40 mA for 30-35 min. The gel was stained for 15-20 min in a Coomassie Brilliant Blue R-250 solution and excess stain was removed by destaining solution.

2.6.3 Surface Plasmon Resonance (SPR) Spectroscopy

Surface Plasmon Resonance (SPR) is a biosensing technique to measure biomolecular interactions in a label free environment. One of the interactants (ligand) is immobilized onto the metal film (Gold layer), whereas the second (analyte) is passed over the surface in a continuous flowing aqueous solution. Plane polarized light is reflected off the opposite side of the metal film. At a certain angle the light excites the electrons in the gold layer generating a surface plasmon and resulting in a loss of reflection. Binding of analyte to the immobilized ligand increases the refractive index and hence the angle at which absorption of energy occurs. This change in angle is relayed in response units (RUs) and is directly proportional to the amount of analyte bound to the ligand. In this work, binding studies between Rab1A (ligand) and SidM (analyte) were carried out using a Biacore X instrument. Different dilutions of Rab1A₁₋₂₁₀ were passed over the surface of a Ni-NTA sensor chip (20 μ L/min flow rate, 25 °C) to immobilize the ligand via its C-terminal His₆-tag until sufficient ligand had bound (corresponding to 200? RU). Thereafter, 1-5 μ M solutions of SidM₃₁₇₋₅₄₅ were passed over the immobilized Rab1A₁₋₂₁₀ to allow for binding analysis.

2.6.4 Isothermal Titration Calorimetry (ITC)

Isothermal Titration Calorimetry (ITC) was also employed to analyze the binding affinity between Rab1A₁₋₂₁₀ and SidM₃₁₇₋₅₄₅. In this work, ITC experiments were performed using an ITC200 Titration Calorimetry System (Microcal, GE Health care). Prior to the

experiment, both protein samples were subjected to buffer exchange (50 mM HEPES pH8.0, 50 mM NaCl) using SEC and concentrated by ultracentrifugation using Vivaspinn-concentrators. All buffers and protein samples were filtered and degassed to avoid air bubbles during the experiment. Cells and the syringe of the ITC200 were extensively washed with buffer (50 mM HEPES pH 8.0, 50 mM NaCl). 40 μ L of the Rab1A₁₋₂₁₀ solution (1000 μ M) was filled into the syringe and titrated against 300 μ L of the SidM₃₁₇₋₅₄₅ solution (100 μ M) present in the sample cell. All titrations were performed at 25 °C, 500 rpm (syringe rotation). 2 μ L were injected per cycle with a total of 18 cycles and 4 s duration between injections. Data were analyzed by Microcal Origin7 software. The peaks obtained after each injection were integrated to calculate the amount of heat absorbed or evolved upon complex formation. The binding affinity constant 'K', the stoichiometry 'n' and the binding enthalpy ' Δ H' were derived by curve fitting using the single set of independent sites model.

2.7 Crystallization

As part of this project both SidM₃₁₇₋₅₄₅ alone and the complex between SidM₃₁₇₋₅₄₅ and Rab1A₁₋₁₇₅ were crystallized. Methods used were sitting-drop and hanging drop vapor diffusion. Preliminary crystallization trials were carried out using a range of commercial screens (Hampton Research and QIAGEN) in Low Profile Greiner 96 well plates by sitting drop vapor diffusion setup. The reservoir consisted of 80 μ L of the screening solution. Crystallization drops were prepared by mixing 200 nL of protein and 200 nL of reservoir solution by Mosquito robot (TTP Labtech Ltd). The crystallization plates were sealed with crystal clear tape and stored at 4 °C, 10 °C and/or 16 °C.

Once suitable starting conditions had been identified, protein crystals were optimized in 24-well plate formats by hanging drop experiments. The reservoir was filled with 500-1000 μ L of reservoir solution and the crystallization drops prepared by mixing 1-2 μ L of protein solution with 1-2 μ L of reservoir solution. The crystallization drop was pipetted onto a siliconised cover slip and inverted over the reservoir with drop facing downwards. Silicone grease was applied to the raised rim of the reservoir to seal each experiment. Parameters that were optimized to improve crystal quality include the protein concentration, precipitant and salt concentrations, the pH of the buffer produce well diffracting crystals.

2.8 X-ray Data Collection

Protein crystals were individually harvested from their mother liquor using a nylon loop, transferred to a suitable cryoprotectant derived from the mother liquor and flash cooled in liquid nitrogen. X-ray diffraction data were collected on a home source comprising a rotating copper anode generator and using a Saturn 944HG charged coupled device (CCD) detector (Rigaku) as well as at the beam line Proxima1-Soleil.

2.9 Data Processing and Structure Solution

X-ray diffraction data of SidM₃₁₇₋₅₄₅ crystals were processed with XDS and scaled with XSCALE (Kabsch 1993), those for Rab1A₁₋₁₇₅/SidM₃₁₇₋₅₄₅ complex HKL-Suite 3000 (Otwinowski and Minor 1997). Further processing of data was carried out using the CCP4 Suite (Collaborative Computational Project 4, 1994). Intensities were converted to structure factor amplitudes using TRUNCATE from CCP4 package. The structure of the Rab1A₁₋₁₇₅/SidM₃₁₇₋₅₄₅ complex was solved by molecular replacement using the structure of the complex DrrA₃₄₀₋₅₃₃/Rab1b₃₋₁₇₄ as a search model in Phaser (Storoni, McCoy et al. 2004). The model from Phaser was refined using restrained refinement in REFMAC5 (Murshudov, Vagin et al. 1997). The model was adjusted manually using COOT (Emsley and Cowtan 2004). The final structure was validated using Molprobit. Protein figures were prepared using PYMOL (<http://pymol.sourceforge.net/>).

3 Results

In this study, full-length and six C-terminally truncated variants of human Rab1A GTPase as well as the central domain of SidM (residues 317-545), a type IVB effector protein from *Legionella pneumophila*, were studied. The genes of interest were cloned into the expression vector pGEX-6P1 and proteins were produced in *E. coli* and purified by affinity, ion exchange and size exclusion chromatography. The crystal structure of Rab1A₁₋₁₇₅/SidM₃₁₇₋₅₄₅ complex was solved by X-ray crystallography and refined to 2.05 Å resolution.

3.1 Human Rab1A, a small GTPase

cDNA for Human Rab1A was provided by Dr. Matthias P. Machner (National Institute of Child Health and Human Development [NICHD], Washington DC, USA. This was transferred to the expression vector pGEX-6P1 (GE Healthcare) coding for an N-terminal GST tag by Ms. Christin Holland (HZI, Braunschweig, Germany) for expression in *E. coli*. As part of this thesis, a C-terminal His₆-tag was added to Rab1A by site-directed mutagenesis (section 2.4.4) to allow purification of C-terminally intact protein by Ni-NTA affinity chromatography.

3.1.1 Production and purification of recombinant Rab1A

For simplicity, the GST and His₆-tagged full-length Rab1A will hereafter be referred to as Rab1A. Rab1A was produced in Rosetta 2 *E. coli* cells overnight at 20 °C following induction with 0.1 mM IPTG. Cells were pelleted, lysed by homogenizer and centrifuged to separate soluble and insoluble fractions. The soluble fraction was applied to glutathione agarose resin and unbound proteins were removed by washing the resin with PBS buffer. The GST fusion tag was cleaved off by adding PreScission protease at 4 °C and incubating overnight. The GST free Rab1A was eluted using PreScission protease cleavage buffer, while GST remained on the column. The yield and purity of the protein were qualitatively analyzed by SDS-PAGE (Fig 3.1). After GST affinity purification, Rab1A was observed to degrade rapidly. This was visualized by SDS-PAGE (Fig 3.1), where Rab1A runs at 23 kDa and degraded product is around 20 kDa. Degradation of Rab1A was assumed to be caused by secreted bacterial host proteases. Prior to purification “Complete” protease inhibitor cocktail tablets, EDTA-free (Roche) were added to all the buffers to avoid degradation. This, however, did not improve the stability of Rab1A.

Figure 3.1: Purification of Rab1A by Glutathione affinity chromatography. Coomassie stained SDS-PAGE analysis of GST-Rab1A purification. Lanes from left to right, 1-GST fusion Rab1A, 2-Overnight proteolytic cleavage of GST fusion Rab1A with PreScission protease, 3 and 4- Elution fractions of Rab1A (Upper band), degradation product of Rab1A (Lower band)

3.1.2 C-terminal deletions of Rab1A

To stabilize Rab1A, 5, 15, 18, 23 and 35 amino acid residues were C-terminally deleted by site-directed mutagenesis using primers designed to retain the His₆-tag - except in the case of Rab1A₁₋₁₇₅ (Fig 3.2). The resulting Rab1A variants were all produced and purified as for full-length Rab1A. Variants Rab1A₁₋₂₀₅, Rab1A₁₋₁₉₅ and Rab1A₁₋₁₈₇ similarly prone to degradation as the full-length protein (Fig 3.3).

Figure 3.2: C-terminal deletions of Rab1A. Rab1A was C-terminally truncated by site-directed mutagenesis. The C-terminal His₆-tag was retained for all variants except Rab1A₁₋₁₇₅.

Figure 3.3: Coomassie stained SDS gel showing the instability of Rab1A₁₋₁₈₇ variant. Lanes from left to right, 1. Protein Marker, 2. GST Rab1A₁₋₁₈₇ fusion protein, 3. Overnight cleavage of GST fusion Rab1A₁₋₁₈₇ with PreScission protease, 4. and 5. Elution fractions of Rab1A₁₋₁₈₇. Degradation of variant Rab1A₁₋₁₈₇ is indicated by a red rectangular box.

3.1.3 Production and purification of stable Rab1A₁₋₁₇₅

As outlined above, a range of C-terminal deletions of Rab1A still resulted in unstable protein. Hence, Rab1A was further C-terminally deleted by adding a stop codon prior to residue 35 by site-directed mutagenesis losing the His₆-tag in the process. Purification of Rab1A₁₋₁₇₅ was as described for full-length Rab1A. Rab1A₁₋₁₇₅ did not show any signs of degradation after GST affinity purification (Fig 3.4A). Rab1A₁₋₁₇₅ eluted as a single peak during size exclusion chromatography (SEC) using a Superdex 75 16/60 SEC column with an elution volume of 77 mL (Fig 3.4B). Relative to standards the elution volume of Rab1A₁₋₁₇₅ corresponds to a molecular weight of 20 kDa confirming Rab1A to be monomeric.

Figure 3.4 Purification profile of Rab1A₁₋₁₇₅ (A) Coomassie stained SDS-PAGE analysis of glutathione affinity purified Rab1A₁₋₁₇₅. Lanes from left to right, 1. GST-Rab1A₁₋₁₇₅ fusion protein; 2. Overnight proteolytic cleavage of the fusion protein with PreScission protease; 3, 4. and 5. In consecutive elution fractions Rab1A₁₋₁₇₅ appears as a single band. (B) SEC elution profile and corresponding SDS gel of Rab1A₁₋₁₇₅. Fractions highlighted by red bar on the SDS gel show pure and stable Rab1A₁₋₁₇₅.

3.2 Type IVB effector protein SidM of *Legionella pneumophila*

3.2.1 Production and Purification of SidM₃₁₇₋₅₄₅

To analyze the interaction of human Rab1A with SidM from *L. pneumophila*, the central domain corresponding to residues 317-545 of SidM was cloned into vector pGEX-6P1. A GST-SidM₃₁₇₋₅₄₅ fusion protein was hence produced in BL21 *E. coli* cells overnight at 37 °C induced with 0.1 mM IPTG. Cells were harvested, lysed by homogenizer and centrifuged to separate soluble and insoluble fractions. The soluble fraction was applied to glutathione agarose resin, unbound proteins washed off and GST-fusion protein cleaved on column with PreScission protease overnight at 4 °C. SDS-PAGE analysis of SidM₃₁₇₋₅₄₅ indicated a stable, undegraded protein (Fig 3.5). SidM₃₁₇₋₅₄₅ was further purified by size exclusion chromatography on a Superdex 75 16/60 column. See Figure 6 for the elution profile and SDS-PAGE analysis. The first two peaks, marked by red and green bars, contain SidM₃₁₇₋₅₄₅ co-eluting with impurities while the third peak (blue bar) contains pure SidM₃₁₇₋₅₄₅ with an elution volume of 72 mL. Compared to protein standards this volume indicates molecular weight of 27 kDa for SidM₃₁₇₋₅₄₅, which matches its size on SDS-PAGE gel (Fig 3.6). SidM₃₁₇₋₅₄₅ was concentrated by ultrafiltration to 13 mg/mL for crystallization trials.

size exclusion chromatography of SidM₃₁₇₋₅₄₅ using a Superdex 75 16/60 column. Peaks one and two, marked by red and green bars contain SidM₃₁₇₋₅₄₅ with other impurities whereas peak 3 indicated by blue bar (elution volume of 72 mL) contains pure SidM₃₁₇₋₅₄₅. Fractions containing pure SidM₃₁₇₋₅₄₅ were pooled and concentrated by Vivaspın. The corresponding SDS-PAGE gel is featured as the right-hand insert.

3.2.3 Crystallization of SidM₃₁₇₋₅₄₅

After final purification of SidM₃₁₇₋₅₄₅ by SEC, the protein was concentrated by ultrafiltration to 15 mg/mL for crystallization. Initial screening for crystallization lead conditions was performed in 96 well plate by sitting drop vapor diffusion. Around a thousand crystallization conditions were screened at both 10 and 16 °C and various protein concentrations. SidM₃₁₇₋₅₄₅ crystals were observed in a condition containing 0.1 M phosphate citrate buffer pH 4.25, 5 % PEG 3000, 12 % 1, 2-propanediol and 10 % glycerol at 16 °C (Fig 3.7A). However, the resultant crystals were in clusters unsuited for single-crystal diffraction experiments. These initial crystals were used to prepare crystallization seeds in crystal optimization trials. Conditions were optimized by varying pH, PEG and protein concentrations, finally yielding individual large crystals (Fig 3.7B). These crystals diffracted X-rays to ~ 3 Å at the Soleil synchrotron (Fig 3.8) and also on an in-house rotating anode generator (Rigaku MicroMax 007 HF) equipped with a CCD detector (Rigaku Saturn944HG). The diffraction data was processed using MOSFLM (Leslie and Powell 2007). Closer inspection of the diffraction pattern indicated SidM₃₁₇₋₅₄₅ crystals to have a modulated structure, meaning the fundamental unit cell can be obtained using strong reflections only. Indexing of these reflections results in a primitive triclinic basis cell with $a = 60$ Å, $b = 151$ Å, $c = 153$ Å, $\alpha = 98^\circ$, $\beta = 101^\circ$ and $\gamma = 101^\circ$. These parameters can be transformed to a body centered orthorhombic lattice with unit cell dimensions $a = 60$ Å, $b = 191$ Å, $c = 229$ Å when incorporating the weaker diffraction spots along C-axis. These satellite reflections are represented by incommensurate vector q (personal communication: Dr. Toine Schreurs, BIJVOET Centre for Biomolecular Research, Utrecht University, Utrecht, The Netherlands). Processing of diffraction data with this larger unit cell resulted in a completeness of 30 %, insufficient for structural analysis. Optimization experiments with detergent and additive screens failed to solve the incommensurate crystal problem.

Figure 3.7: Crystallization of SidM₃₁₇₋₅₄₅: A) An initial sitting drop vapor diffusion screen yielded small clustered crystals. B) Micro-seeding using initial crystals as seeds by hanging drop method resulted in plate-like large crystals that diffracted to 3.0 Å.]

Figure 3.8: A diffraction image of SidM₃₁₇₋₅₄₅ crystal. The blue circle indicates the resolution limit of 3.0 Å

3.3 Complex formation of SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅

3.3.1 Purification and analysis of SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ complex

SidM of *L. pneumophila* was previously shown to interact with the human, small GTPase Rab1A (Machner *et al*, 2007). Structural information for Rab1A was available while the structure of SidM

was unknown. To understand the structural details of the SidM interaction with Rab1A, the central domain of SidM (residues 317-545) was complexed with Rab1A (Fig 3.9). SidM and Rab1A were purified separately by glutathione agarose affinity chromatography (See chapter 2.3.3). Fractions of both proteins eluted following cleavage from GST were analyzed by SDS-PAGE (Fig 3.9A). SidM₃₁₇₋₅₄₅ and Rab1A₁₋₁₇₅ were mixed and incubated at 4 °C to allow complex formation. The resulting Rab1A₁₋₁₇₅/SidM₃₁₇₋₅₄₅ complex was purified by Size Exclusion Chromatography to remove impurities and uncomplexed proteins, and also to establish whether dissociation of the complex occurs. Fig 3.9B combines the chromatogram and SDS-PAGE. As expected, the complex eluted first (highlighted by a red bar, ~47 kDa) followed by excess SidM₃₁₇₋₅₄₅ (magenta bar). Clearly Rab1A₁₋₁₇₅ and SidM₃₁₇₋₅₄₅ form a tight, 1:1 complex (Fig 3.9B)

Figure 3.9: Purification profile of SidM/Rab1A complex

(A) Glutathione affinity purification of SidM and Rab1A. Elution fraction of SidM and Rab1A were analyzed by SDS-APGE. (B) Size exclusion chromatography of SidM/Rab1A complex. Coomassie stained SDS-PAGE gel and chromatogram showing the formation of complex, fractions highlighted in red bar indicates SidM/Rab1a complex eluted with an elution volume of 64 mL corresponds to 47 kDa and fractions highlighted in magenta bar indicates excess SidM

3.3.2 Stability of SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ complex

The SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ complex was further purified by anion exchange chromatography (AEC). In addition this method would further establish the tightness of the complex. The pH was chosen to allow excess SidM₃₁₇₋₅₄₅ to elute in the flow through rather than binding to the column while the complex did bind and was thereafter eluted using a linear NaCl gradient. The AEC chromatogram (Fig 3.10) reveals a single elution peak, which SDS PAGE analysis confirmed to correspond to homogenous Rab1A₁₋₁₇₅/SidM₃₁₇₋₅₄₅ complex. Thereafter the Rab1A₁₋₁₇₅/SidM₃₁₇₋₅₄₅ complex was further purified by SEC to remove excess NaCl prior to crystallization.

Figure 3.10: Anion exchange chromatography of SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ complex

Separation of excess SidM₃₁₇₋₅₄₅ from SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ complex. SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ complex was applied to the anion exchanger and eluted by salt gradient from 0 to 100mM NaCl. Unbound SidM₃₁₇₋₅₄₅ came out in the flow through indicated by red bar and elution fractions of SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ complex were indicated by green bar.

3.3.3 Co-expression of SidM₃₁₇₋₅₄₅ and Rab1A₁₋₁₇₅

To speed up purification of SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ the two proteins were co-expressed in *E. coli* BL21 and Rosetta 2 to allow stable complex formation *in situ*. For this, the gene encoding SidM₃₁₇₋₅₄₅ was cloned into the vector pETM-30 by a restriction free cloning (see section 2.4.5 for details on the method). For Rab1A₁₋₁₇₅ production the existing pGEX-6P1 (Fig 3.11A & B). As the vector pETM-30 carries kanamycin and pGEX-6P1 ampicillin antibiotic resistance genes, retention of both plasmids can be enforced by adding both antibiotics. Co-expressed SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ complex was purified by GST affinity chromatography followed by SEC. Production of soluble SidM₃₁₇₋₅₄₅ and Rab1A₁₋₁₇₅ was analyzed on SDS-PAGE (Fig 12A). SidM₃₁₇₋₅₄₅ and Rab1A₁₋₁₇₅ co-eluted from the glutathione agarose column. SidM₃₁₇₋₅₄₅ was, however, markedly more strongly produced than Rab1A₁₋₁₇₅ (Fig 3.12A). Fractions containing the complex were pooled and further purified by SEC.

Figure 3.11: Co-expression of SidM₃₁₇₋₅₄₅ and Rab1A₁₋₁₇₅. (A) Re-cloning of *sidM* into pETM-30 vector. (B) Co-expression of pGEX-6P1Rab1A₁₋₁₇₅ and pETM-30 SidM₃₁₇₋₅₄₅ into Rosetta 2.*E. coli* cells

(B) Coomassie stained SDS-PAGE of SEC of SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅. Fractions highlighted by the red rectangle contain SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ (C) SDS-PAGE showing concentrated SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ after SEC.

3.4 Surface Mutagenesis of Rab1A

3.4.1 Rab1A^{K55S-K58S} and Rab1A^{E168A-K170S-K171A-R172S} variants

Following numerous failed attempts to crystallize the SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ complex, the method of entropy reduction was used on Rab1A to increase the likelihood of crystallization. Long, flexible surface residues such as lysine and arginine were replaced by short, less flexible alanines and serines. Two variants of Rab1A were constructed by site-directed mutagenesis: the double variant K55A-K58S and the quadruple variant E168A-K170S-K171A-R172S. Production and purification of the variants were carried out as for full length Rab1A. However, neither of these variants resulted in crystals. Coincidentally though SEC (Fig 3.13) and ITC experiments (Fig 3.24) demonstrated the variant Rab1A^{K55A-K58S} to be strongly impaired for SidM₃₁₇₋₅₄₅ binding compared to wild type Rab1A.

Figure 3.13: SEC purification profile of Rab1A^{K55A-K58S}/SidM₃₁₇₋₅₄₅. Rab1A^{K55A-K58S} and SidM₃₁₇₋₅₄₅ are largely separated during SEC purification. Fractions of the first SEC peak highlighted by the red bar contain SidM₃₁₇₋₅₄₅ together with larger impurities. The green bar marks SidM₃₁₇₋₅₄₅ with a small amount of retained Rab1A^{K55A-K58S}. The pink bar highlights fractions of the third peak essentially containing unbound Rab1A^{K55A-K58S}.

3.5 Structure of SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ complex

3.5.1 Crystallization of SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅

As part of this thesis, six truncation variants of human Rab1A were generated. Each was screened over a wide variety of conditions to generate crystals in complex with SidM₃₁₇₋₅₄₅ with the aim of solving the crystal structure of the complex. All truncation mutants tightly bind SidM₃₁₇₋₅₄₅. However only the complex consisting of SidM₃₁₇₋₅₄₅ and Rab1A₁₋₁₇₅ and where both genes were co-expressed in *E. coli* was successfully crystallized. The SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ complex was concentrated to 15 mg/mL and crystallization lead conditions were screened for using commercial

screens by sitting drop vapor diffusion experiments in 96 well plates. Crystals of SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ complex were finally observed to grow in wells containing 27.5 % PEG 400 and 0.1 M sodium citrate pH 5.3 at 10 °C (Fig 3.14A). These clustered crystals were optimized by varying the pH and precipitant concentrations in a 26 (6x4) well hanging drop vapor diffusion crystallization plate. Optimization finally resulted in large single crystals in 35 % PEG 400 and 0.1 M sodium citrate pH 5.5 (Fig 3.14B). As the reservoir solution already had the properties of a cryo-protectant, crystals were directly harvested from the drops, cryo-cooled and subjected to X-ray analysis.

Figure 3.14: Crystals of the SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ Complex

(A) Initial, slightly intergrown crystals of SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅. (B) Optimized SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ crystals grown in a hanging drop experiment yielded a single crystal of sufficient size for X-ray diffraction experiments.

3.5.2 Data collection and processing

X-ray diffraction data for SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ crystals were collected in-house on a rotating anode generator (Rigaku MicroMax-007HF) and CCD detector (Rigaku Saturn944HG). The diffraction data were indexed, integrated and scaled using the software package HKL3000 (Otwinowski and Minor 1997). The crystals diffracted X-rays to 2.05 Å resolution and crystals were found to belong to the trigonal space group R3 with unit cell dimensions $a=b=105.0$ Å and

$c=118.6 \text{ \AA}$ $\alpha = \beta = 90^\circ$ and $\gamma = 120^\circ$. Matthews's coefficient analysis (Matthews 1968) suggested a packing parameter $V_M = 2.68 \text{ \AA}^3/\text{Da}$ corresponding to a solvent content of 54%. This in turn implied a crystal packing with of one SidM/Rab1A dimer per asymmetric unit.

Structure factors were phased by molecular replacement using the programme PHASER (Storoni, McCoy et al. 2004) and the complex of DrrA₃₄₀₋₅₃₃/Rab1b₃₋₁₇₄ as a search model. The single solution from PHASER was refined by restrained refinement protocol in REFMAC5 (Murshudov, Vagin et al. 1997) alternated cyclically with manual adjustment of the model addition of water molecules in COOT (Emsley and Cowtan 2004). This procedure gradually improved the model resulting in a final model with R and R_{free} values of 16.0 and 19.0 % respectively.

Figure 3.15: Electron density map of the SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ Complex after final refinement of the structure. The P-loop of Rab1A is depicted in magenta, SidM in cyan.

3.5.3 Structure of Rab1A₁₋₁₇₅

Structurally Rab1A shares structural features with other small GTPases (See chapter 4.2) such as the Switch I and Switch II motifs as well as the P-loop. Rab1A₁₋₁₇₅ displays mixed α -helical and β -sheet structure: a central 6-stranded β -sheet comprised of five parallel (β_{1R} , β_{3R} , β_{4R} , β_{5R} and β_{6R} – where the subscript R stands for Rab1A) and one anti-parallel β -strand (β_{2R}) is surrounded by 6 α -helices (α_{1R} to α_{6R}). The ten connecting loops L1 to L10 are correspondingly denoted β_{1R} - α_{1R} , α_{1R} - α_{2R} , α_{2R} - β_{2R} , etc. Five N-terminal residues of Rab1A₁₋₁₇₅ are remnants of the PreScission protease cleavage site. Part of the loop between β_{6R} and α_{6R} is disordered (Figure 3.16). Structural

elements contributing to switch I (blue in Figure 3.16) include L2, α_{2R} and L3 (residues 34 to 45). Switch II (red in Figure 3.16) is comprised of L5, α_{3R} and L6 (residues 63 to 80). The P-loop (magenta in Figure 3.16) is located in L1 spanning residues 16 and 17.

Figure 3.16: Structure of Rab1A₁₋₁₇₅

Rab1 is shown in green, Switch I domain is represented in blue, Switch II in red, P-loop in magenta and inter switch regions in salmon.

In the crystal structure of the SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ complex, Rab1A₁₋₁₇₅ displays mixed α -helical and β -sheet structure: a central 6-stranded β -sheet comprised of five parallel (β_{1R} , β_{3R} , β_{4R} , β_{5R} and β_{6R} – where the subscript R stands for Rab1A) and one anti-parallel β -strand (β_{2R}) is surrounded by 6 α -helices (α_{1R} to α_{6R}). The ten connecting loops L1 to L10 are correspondingly

denoted $\beta 1_R-\alpha 1_R$, $\alpha 1_R-\alpha 2_R$, $\alpha 2_R-\beta 2_R$, etc. Five N-terminal residues of Rab1A₁₋₁₇₅ are remnants of the PreScission protease cleavage site. Part of the loop between $\beta 6_R$ and $\alpha 6_R$ is disordered (Fig 3. 16A&B). Structurally Rab1A shares structural features with other small GTPases (See section 4.2) such as the Switch I and Switch II motifs as well as the P-loop. Structural elements contributing to switch I include L2, $\alpha 2_R$ and L3 residues 34 to 45. Switch II is comprised of L5, $\alpha 3_R$ and L6 residues 63 to 80. The P-loop is located in L1 spanning residues 16 and 17.

3.5.3 Structure of SidM₃₁₇₋₅₄₅

SidM₃₁₇₋₅₄₅ has a unique structural fold and is a purely α -helical structure comprising eight α -helices (denoted $\alpha 1_S$ to $\alpha 8_S$, where “subscript S” indicates the component SidM). The α -helices are connected by seven loops denoted L_A to L_G corresponding to $\alpha 1_S-\alpha 2_S$, $\alpha 2_S-\alpha 3_S$, $\alpha 3_S-\alpha 4_S$ etc. SidM₃₁₇₋₅₄₅ forms a two-layered structure, in which two parallel α -helices $\alpha 4_S$ and $\alpha 5_S$ constitute the upper layer. This layer coincidentally is the primary contact surface for Rab1A. The lower layer is formed by the roughly parallel α -helices $\alpha 1_S$, $\alpha 2_S$, $\alpha 6_S$ and $\alpha 7_S$. The two α -helical layers are oriented at an angle of 90 ° to each other. The other two small helices $\alpha 3_S$ and $\alpha 8_S$ are located at the end of $\alpha 4_S$ and $\alpha 5_S$ respectively (Figure 3.17).

Figure 3.17: Structure of SidM₃₁₇₋₅₄₅ rendered in cyan, helices indicated by numbers

3.5.4 The SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ Complex

SidM and Rab1A form a stoichiometric complex in which SidM binds predominantly to the Switch I, Switch II and P-loop regions of Rab1A (Figure 3.18). SidM binding induces conformational changes on Rab1A structure, where Switch I is displaced away from the nucleotide binding site and Switch II adopts ordered conformation (Detail explanation in section 4.2).

Figure 3.18: The Crystal Structure of the SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ Complex. Cartoon representation of the SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ complex. SidM₃₁₇₋₅₄₅ interacts with the Switch I, Switch II and P-loop of Rab1A₁₋₁₇₅. Rab1A₁₋₁₇₅ is represented in green, with Switch I in blue, Switch II in red, the P-loop in magenta and SidM₃₁₇₋₅₄₅ in cyan. The black dashed line in the Rab1₁₋₁₇₅ structure indicates the disordered loop.

3.5.5 Interface of the SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ Complex

In the crystal structure of the complex, the interactions between the SidM₃₁₇₋₅₄₅ and Rab1A₁₋₁₇₅ bury surface accessible area of 1816Å² as calculated by the PISA server (Krissinel and Henrick, 2007). Structural elements involved in complex formation are the N-terminal loop, β_{1R}, β_{2R}, Switch I, Switch II and P-loop of Rab1A₁₋₁₇₅ and the α_{2S}, α_{4S}, α_{5S}, α_{6S} and α_{8S} helices and the loops L_D, L_E, L_F of SidM₃₁₇₋₅₄₅ (Figure 3.19).

Figure 3.19: Surface representation of the SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ Complex. (A) Rab1A and SidM are shown in surface representation. Switch I of Rab1A is shown in blue, Switch II in red, P-loop in magenta and other regions in green and SidM in cyan (B) The Rab1A interacting region of SidM is shown in surface representation and Rab1A is in cartoon presentation

Based on the contact regions of Rab1A₁₋₁₇₅, the interactions of the complex can be divided in to four sections

3.5.6 Switch I of Rab1A₁₋₁₇₅ contacts α_2 , α_5 , α_6 and L_F of SidM₃₁₇₋₅₄₅

In the crystal structure of SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ complex, the larger part of the switch I region of Rab1A (residues 34 to 48) as well as L2 (α_{1R} - α_{2R}), α_{2R} and L3 (α_{2R} - β_{2R}) contact the upper layer α_{5S} and the bottom layer α_{2S} , α_{6S} and L_F (α_{6S} - α_{7S}) of SidM (Figure 3.18).

Figure 3.20: Interactions between Rab1A Switch I and SidM. (A) Hydrogen bond interactions between Switch I of Rab1A and SidM. Rab1A residues are represented in green, those of SidM in black. Hydrogen bonds are represented by black dotted lines. (B) Hydrophobic interactions between Switch I of Rab1A and SidM. Grey lines indicate hydrophobic interactions.

Contacts include several hydrogen bonds and hydrophobic interactions. Loop L2 (α_{1R} - α_{2R}) residues T34_R (O), E35_R (O ϵ 1, O ϵ 2) and S36_R (N, O γ) of Rab1A form strong direct and water-mediated hydrogen bond interactions with L_F (α_{6S} - α_{7S}) residues D480_S (N) and S483_S (O γ) of SidM Fig (3.20A). The α_{2R} and L3 of Rab1A bears several hydrophobic residues Y37_R, I38_R, I41_R, V43_R and F45_R, which makes extensive hydrophobic interactions with α_{5S} and α_{6S} residues A345_S, V436_S, M439_S, F474_S and V478_S of SidM (Fig 3.20B). The structural changes in the Switch I region of Rab1A, upon SidM binding is discussed in detail in section 4.2

3.5.7 Switch II contacts of Rab1A₁₋₁₇₅ with SidM₃₁₇₋₅₄₅

Figure 3.21: Interactions between Rab1A Switch II and SidM. (A) Hydrogen bonding interactions of Switch II of Rab1A and SidM. Rab1A residues are represented in Green and SidM residues in Black respectively. Hydrogen bonds are represented in black dotted lines. (B) Hydrophobic interactions between Switch II of Rab1A and SidM. Grey lines indicate hydrophobic interactions.

The structural elements L5, α_{3R} and L6 of Rab1A Switch II (residues 63-80) extensively interact with α_{4S} , α_{5S} , α_{8S} and L_E of SidM through hydrogen bonds and hydrophobic interactions (Fig

3.21A&B). Helix α_{3R} of Rab1A form strong interactions with L_E and α_{5S} of SidM through several hydrogen bonds between negatively charged Q68_R of Rab1A with N451_S (N) and R453_S (NH1) of SidM. In addition, positively charged R69_R of Rab1A interacts strongly with A441_S, D445_S, L448_S, S449_S, A454_S and Q452_S of SidM through several direct and water mediated hydrogen bonds (Fig 3.21A). Apart from these hydrogen-bonding interactions, L6 and α_{4R} of Rab1A also interact with α_{4S} , α_{5S} and L_E of SidM through hydrophobic interactions. F70_R of Rab1A forms multiple hydrophobic interactions with L406_S, W410_S, M444_S and A454_S of SidM, where W410_S forms aromatic π -stacking interaction with F70_R (Fig 3.21B).

3.5.8 P-Loop and other contacts of Rab1A₁₋₁₇₅ with SidM₃₁₇₋₅₄₅

Phosphate binding loop L1 of Rab1A (residues D16 and S17) contacts L_E of SidM through a salt bridge (D16_R O δ 1/O δ 2 to R453_S N ζ 1/N ζ 2) and two hydrogen bonds (S17_R N/O to N451_S N δ 2/O δ 1) (Fig 3.22).

Figure 3.22: P-loop interactions of Rab1A₁₋₁₇₅ with SidM₃₁₇₋₅₄₅. P-loop residues of Rab1A are coloured magenta, SidM residues cyan. Hydrogen bonds are indicated by black dotted line.

Apart from the Switch I, II and P-loop of Rab1A, other regions are also involved in the interaction

with SidM (Fig 3.23). Thus the N-terminus of Rab1A contacts L_D of SidM through hydrogen bonds (N2_R N \cdots L423_S O; N2_R N δ 2 \cdots T424_S O; Y5_R O ζ \cdots T422_S O; Y5_R O ζ \cdots S426_S O γ ; K10_R N ζ \cdots A421_S O and R418_S O; Fig 23A) and hydrophobic interactions (L8_R = A421_S and Y5_R = L423_S; Fig 3.23B). Similarly, L2_R hydrogen bonds L_D (D31_R O δ 2 \cdots T427_S O γ ; D31_R O δ 2 \cdots T427_S O; and Y33_R O \cdots S426_S O [water mediated]) while β 3_R interact with α 5_S (K58_R NZ \cdots S426_S O γ and Q60_R N ϵ 2 \cdots S426_S O [water mediated]).

Figure 3.23: Other interactions between Rab1A and SidM. (A) Hydrogen bonding interactions of Rab1A and SidM. Rab1A residues are represented in green and SidM residues in black. Hydrogen bonds are represented by black dotted lines. **(B)** Hydrophobic interactions between Rab1A and SidM. Grey dashed-dotted lines indicate hydrophobic interactions.

3.6 Isothermal Titration Calorimetry (ITC) Measurements

The affinity of SidM₃₁₇₋₅₄₅ for Rab1A₁₋₁₇₅ was analyzed and quantified by Isothermal Titration Calorimetry (ITC) to complement earlier qualitative analyses by size exclusion chromatography (SEC). ITC is particularly sensitive and powerful in that it provides all the binding parameters such as binding affinity (K), binding stoichiometry (n), and binding enthalpy (ΔH) in a single experiment.

ITC experiments were performed on a Microcal ITC-200. Data is processed and evaluated using Microcal software integrated in Origin 7. SidM₃₁₇₋₅₄₅, and Rab1A (full length and variants) were purified and final buffer exchange was performed with 50 mM HEPES (pH 8.0) and 150 mM NaCl using a Superdex 75 1030 SEC column. The protein samples were concentrated to 100-1000

μM by vivaspin ultra centrifugal filter units of 10kDa molecular weight cut off and degassed for 10 minutes prior to any experiment.

In this experimental approach two states of Rab1A were used for the interaction analysis with SidM₃₁₇₋₅₄₅. In the first state, Rab1A: GDP was titrated to SidM₃₁₇₋₅₄₅. In the second state Rab1A: GDP was treated with 20 mM EDTA during all the purification steps to chelate Mg^{2+} and remove GDP.

3.6.1 State A- Rab1A: GDP/SidM₃₁₇₋₅₄₅

The binding affinity of Rab1A: GDP to SidM₃₁₇₋₅₄₅ was analyzed by titrating 18 x 2 μL injections of 1000 μM Rab1A: GDP from the syringe into the calorimetric cell containing 300 μL of 100 μM SidM₃₁₇₋₅₄₅ at 25 °C. Fig 3.24A shows the ITC titration curves of Rab1A: GDP to SidM₃₁₇₋₅₄₅. Each peak from the upper panel, in pointing upwards, represents the amount of heat absorbed upon binding of Rab1A to SidM₃₁₇₋₅₄₅, indicating the reaction to be endothermic. The lower panel plots the integrated heat from each injection against the molar ratio of Rab1A to SidM₃₁₇₋₅₄₅. The binding affinity constant 'K', stoichiometry 'n' and binding enthalpy were derived by curve fitting using a "single set of independent sites" model. Analysis of the ITC data for Rab1A: GDP to SidM₃₁₇₋₅₄₅ generated the dissociation constant K_d of 790nM. Thermodynamic parameters obtained from the curve fitting are indicated in Table 3.1 .

3.6.2 State B: EDTA treatment of Rab1A/SidM₃₁₇₋₅₄₅

Recent studies have shown that, Rab1 binds SidM₃₁₇₋₅₄₅ with high affinity in its GDP-free state. In this study, Rab1A: GDP was treated with 20 mM EDTA during all the purification steps to chelate the Mg^{2+} and thereby reduces the binding affinity of GDP. In the final purification step, EDTA was removed by exchanging the buffer by 50 mM HEPES pH 8.0 and 150 mM NaCl. ITC experiments were performed similarly to those for Rab1: GDP (State A) to SidM₃₁₇₋₅₄₅. Interestingly, the binding affinity of SidM₃₁₇₋₅₄₅ for EDTA-treated Rab1A was two-fold higher than Rab1A: GDP: Mg^{2+} (Fig 3.24B). Again the binding of Rab1A to SidM₃₁₇₋₅₄₅ is an endothermic. In the lower panel the integrated heat from each injection is plotted against the molar ratio of Rab1A to SidM₃₁₇₋₅₄₅. Curve fitting indicates dissociation constant K_d of 420 nM for State B EDTA: Rab1A to SidM₃₁₇₋₅₄₅. Other derived thermodynamic parameters are listed in Table 3.1.

3.6.3 Effect of Rab1A^{K55A-K58S} variant on binding affinity with SidM

Prior to solving the structure of the Rab1A₁₋₁₇₅/SidM₃₁₇₋₅₄₅ complex, Rab1A was surface engineered to facilitate its crystallization. As part of this strategy, surface residues K55 and K58 were exchanged by A55 and S58 by site-directed mutagenesis. Unexpectedly, SEC analysis indicated this variant to have a decreased affinity for SidM (Fig 3.13). The crystal structure of the Rab1A₁₋₁₇₅/SidM₃₁₇₋₅₄₅ complex, confirms K58 of Rab1A to contribute to the interaction with SidM₃₁₇₋₅₄₅ (Fig 3.25B). An ITC experiment undertaken to quantify the effect indicated a ten-fold decrease in affinity of Rab1A^{K55A-K58S} for SidM compared to the wild-type protein (Fig 3.25 A) Thermodynamic binding parameters are listed in Table 3.1.

A. EDTA treated Rab1A^{K55A-K58S}/SidM₍₃₁₇₋₅₄₅₎**B. Rab1A K58_R contact with S426_S of SidM₍₃₁₇₋₅₄₅₎**

The Top panel shows the raw data produced by titrating 1000 μM of Rab1A^{K55AK58S} variant to 100 μM of SidM₃₁₇₋₅₄₅. The Bottom panel represents the integration of above peaks against the molar ratio of Rab1A^{K55A-K58S} to SidM₃₁₇₋₅₄₅. (B) The interaction of K58 of Rab1A (green) with S426 of SidM₃₁₇₋₅₄₅ (cyan) from the SidM₃₁₇₋₅₄₅/Rab1A₁₋₁₇₅ crystal structure.

3.6.4 Effect of Rab1 variants E35A, Y37A and I41A on binding to SidM

Key residues of Rab1A₁₋₁₇₅ involved in the interaction with SidM₃₁₇₋₅₄₅ were identified from the crystal structure of Rab1A₁₋₁₇₅/SidM₃₁₇₋₅₄₅: E35_R, Y37_R and I41_R from the switch I region of Rab1A were classified as critical for the interaction with SidM₃₁₇₋₅₄₅ (Fig 3.20A&B). These residues were replaced by alanines by site-directed mutagenesis and corresponding pure samples prepared as described for wild-type Rab1A. The interaction of SidM₃₁₇₋₅₄₅ with Rab1 variants was analyzed by ITC as for wild-type Rab1A. ITC results reveal that all three Rab1A variants E35A, Y37A and I41A result in a significant decrease in the affinity towards SidM₃₁₇₋₅₄₅ (Fig 3.26A&B and Fig 3.27). The details of binding affinity are summarized in the Table 3.1.

4 Discussion

4.1 SidM Manipulates Rab1A Function for *Legionella pneumophila* Survival

Rab1 is a small GTPase that regulates intracellular trafficking between the endocytosolic reticulum (ER) and the Golgi complex (Plutner, Cox et al. 1991; Tisdale, Bourne et al. 1992; Pind, Nuoffer et al. 1994; Wilson, Nuoffer et al. 1994; Somsel Rodman and Wandinger-Ness 2000; Moyer, Allan et al. 2001). In common with other GTPases, cytosolic Rab1 is normally kept in an inactive state by a dedicated GDP-dissociation inhibitor (GDI). To activate Rab1, a GDI-displacement factor (GDF) is required to remove the GDI before a GTP exchange factor (GEF) can induce the release of GDP to allow for subsequent uptake of GTP and activation of Rab1. SidM is a Type Four Secretion System effector protein from *L. Pneumophila* that has both GEF and GDF activity for Rab1GTPase (Machner and Isberg 2006). SidM recruits Rab1 to the *Legionella*-containing vacuole (LCV) as part of generating a specialized vacuole that resembles the host's rough endoplasmic reticulum. Within this vacuole *L. pneumophila* creates a replication niche allowing it to evade destruction by lysosomal fusion (Machner and Isberg 2006; Murata, Delprato et al. 2006).

Prior to the initiation of this study, no structural information for SidM was available. To understand the SidM/Rab1 complex at the atomic level, the central domain of SidM₃₁₇₋₅₄₅ and Rab1A₁₋₁₇₅ were each purified and co-crystallized. Complex formation of SidM/Rab1 was analysed by SEC and ITC experiments. The structure of the SidM/Rab1A complex was determined revealing that the GEF domain of SidM is structurally distinct from known eukaryotic GEFs. The structure of the complex further revealed that SidM induces several conformational changes in Rab1A to facilitate GDP release. ITC experiments show that SidM has a higher affinity for GDP-free Rab1A compared to Rab1:GDP.

4.2 SidM Induces Structural Changes on Rab1A

To identify SidM-induced rearrangements in Rab1A, Rab1A:GDP (PDB ID 2FOL) was superimposed on Rab1A from the Rab1A/SidM complex revealing a root mean square difference (RMSD) of 1.84 Å for C- α atoms. Major structural changes involve α 1_R, P-loop, Switch I, Switch II and the β 5_R- α 5_R loop regions of Rab1A (Fig 4.1C).

4.2.1 Structural mechanism of nucleotide exchange by SidM

Rab GTPases bind GDP/GTP strongly, and GEFs decrease their binding affinity by inducing structural changes on Rab GTPases to catalyse nucleotide release (Schoebel, Blankenfeldt et al. 2010). Significant structural changes of Rab1A include the unravelling of $\alpha 1_R$ (residues 25-30) to form an extended loop and the translocation of Switch I away from the nucleotide-binding pocket—through several hydrophobic and hydrogen bond interactions with SidM. The central loop region of switch I (residues 36-41) adopts an α -helical conformation. Tyr33 and Glu34 in the switch I region bind the guanidine and sugar groups of the GDP in the Rab1:GDP structure and are significantly dislocated by about 21 and 28 Å respectively upon SidM binding. In the Rab:GDP structure, carbonyl oxygen (O) of I38 is involved in the interaction with Mg^{2+} and phosphate via a water molecule, whereas in the complex structure I38 is dislocated by about 17.2 Å (Fig 4.1B).

The P-loop of Rab1A consists of a conserved phosphate and Mg^{2+} binding motif (Vetter and Wittinghofer 2001). Mg^{2+} are essential for high affinity binding of GDP/GTP to the Rab GTPases (Hall and Self 1986). In the structure of Rab1:GDP, Lys21 of the P-loop binds the β -phosphate of GDP and Ser22 coordinates the Mg^{2+} . In the SidM/Rab1A complex, by contrast, SidM hydrogen bonds Asp16 and Ser17 moving Lys21 and Ser22 of the P-loop away from the phosphate and Mg^{2+} -binding sites, reducing the Rab1A affinity towards Mg^{2+} and thereby weakening the binding affinity for GDP.

In the Rab GTPase:GDP complexes, the switch II region is highly disordered (Eathiraj, Pan et al. 2005). In the structure of SidM/Rab1A, switch II is stabilized by multiple interactions with SidM. In Rab1:GDP, Asp63 of switch II coordinates Mg^{2+} via a water molecule. In the SidM/Rab1A complex, by contrast Asp63 forms a salt bridge to Lys21 of the P-loop thereby abolishing the interaction with Mg^{2+} and ultimately results in the decrease binding affinity of Rab1 for GDP (Fig 4.1B). Other SidM-induced changes include shifts of Rab1A loops $\beta 2_R$ - $\beta 3_R$ by 4.9Å (by the engagement of Lys58) and $\beta 5_R$ - $\alpha 5_R$ to a position that is occupied by guanosine base in Rab1A: GDP structure.

The described structural changes of Rab1A brought about by SidM binding combine to open the nucleotide binding pocket to release GDP explaining the GEF activity of SidM. The SidM mechanism of stabilizing nucleotide-free Rab1A is similar to that of other Rab:GEF complexes.

While our analyses were in progress, two competing groups reported crystal structures of Rab1 in complex with GEF domain of SidM (Schoebel, Blankenfeldt et al. 2010; Suh, Lee et al. 2010). To compare our SidM/Rab1A complex to the other two, the latter were

structurally aligned with our structure. This procedure yielded RMSD values of 0.51 and 0.59 Å for all C- α atoms of both proteins respectively. The low RMSDs imply essentially identical complexes, despite distinct crystal packing arrangements for each. Correspondingly, no major conformational changes are observed between these structures. Minor structural differences are likely to be caused by the crystal packing arrangement (Fig 4.2).

Figure 4.1: SidM-Induced Conformational changes in Rab1A (A). Conformational changes in Rab1A induced by SidM are identified by comparing Rab1A from its complex with SidM (green) to Rab1A:GDP (grey). Motifs Switch I, Switch II and P-loop are respectively shown in blue, red and magenta. Mg^{2+} and GDP are depicted in ball and stick representations. (B). left: Repositioning of Switch I and stabilization of P-loop in Rab1A/SidM; right: Mg^{2+} and GDP binding mode in Rab1A:GDP. (C) Superimposition of Rab1A:GDP (grey) and Rab1A from SidM/Rab1A.

Figure 4.2: Alignment of SidM/Rab1A structure against other published structures of SidM/Rab1A (PDB ID: 2WWX & 3JZA). SidM/Rab1A is represented in green, 2WWX in grey and 3JZA in light blue

4.3 SidM affinity for nucleotide-free Rab1A is higher than for Rab1A:GDP

By interacting with the β - and γ -phosphate groups of GDP and GTP, Mg^{2+} ensures high affinity of Rab GTPases for these nucleotides (Hall and Self 1986; Goody, Pai et al. 1992). Exogenous EDTA removes Mg^{2+} from Rab GTPases inducing conformational changes that reduce affinity for GDP. GEFs bind nucleotide-free GTPases with higher affinity than nucleotide bound GTPases (Lai, Stubbs et al. 1994). In this study, Rab1A:GDP was treated with 20 mM EDTA during purification steps to remove Mg^{2+} . Prior to ITC experiments, the buffer was exchanged with Mg^{2+} - and EDTA-free buffer. The dissociation constant for SidM/Rab1A:GDP was found to be 700 nM (Fig 3.24A). By comparison the affinity of SidM for EDTA-treated Rab1A is increased roughly two-fold ($K_D = 423$ nM) (Fig 3.24B) confirming that the affinity of SidM for GDP-free Rab1A is higher than for GDP-bound Rab1A (Schoebel, Blankenfeldt et al. 2010). However, other studies have quantified the K_D for the SidM/GDP-free Rab1A to be in the pM range, implying that dissociation of GDP from Rab1A in our experiments was incomplete. Nevertheless, we do demonstrate that EDTA-induced loss of GDP does affect SidM affinity for Rab1A.

4.4 Role of Switch I in SidM binding

This and previous structural analyses of SidM/Rab1A have revealed that SidM predominantly interacts with switch I region of Rab1A dramatically changing its conformation. To assess the contribution of individual amino acids, Glu35, Tyr37 and Ile41 were substituted by alanine through site directed mutagenesis. Substituting Glu35 by alanine eliminates the hydrogen bonds linking Glu35 to Asp480 and Ser483 of SidM (Fig 3.20). ITC experiments correspondingly indicate that the affinity of SidM for Rab1A^{E35A} is decreased ~four-fold relative to wild type Rab1A (Fig 3.27). The affinity of SidM for variant Rab1A^{Y37A} is reduced ~15 fold (Fig 3.26A) possibly due to the loss of hydrophobic interactions with SidM residues Ala435, Phe474, Val478, Met439 and Asn373 (Fig 3.20B). Similarly, SidM affinity for Rab1A^{I41A} is decreased ~30-fold (Fig 3.24B) probably due to the loss of hydrophobic and hydrogen bonding contact with Ala435, Met439, His376 and Lys438 of SidM (Fig 3.20A&B). Aligning different Rab sequences reveals that switch I residues Glu35, Tyr37 and Ile48 targeted by SidM are not conserved in other Rabs (Machner and Isberg 2006). This implies that Rab1A is highly specific for SidM.

Our site-directed mutagenesis and ITC experiments have shown that other amino acids at these positions resulted in decrease binding affinity of SidM for Rab1A. These findings imply that the switch I region is important for SidM binding.

4.4 Comparison of SidM/Rab1A with other GEF/Rab Complexes

Crystal structures of five eukaryotic GEFs in complex with nucleotide free Rab GTPases are currently available: Mss4/Rab8, Vps9/Rab21, Sec2/Sec4, TRAPP/Ypt1 and DENN/Rab27 [(Itzen, Pylypenko et al. 2006; Delprato and Lambright 2007; Dong, Medkova et al. 2007; Chin, Cai et al. 2009), 2FU5, 2OT3, 2OCY, 3CUE]. SidM of the SidM:Rab1A complex presented in this study, does not share any obvious structural similarities with the remaining GEF domains. Nevertheless, the GEF mechanism of SidM is related to that of the other GEFs. Most importantly, SidM induces GDP-release exclusively through conformational changes in Rab1A, but without directly interacting with the nucleotide binding residues as observed in other GEFs.

Mss4 was shown to have low GEF activity for Rab8 relative to other GEFs. In the crystal structure of the nucleotide-free Mss4/Rab8 complex, Mss4 recognizes the switch I and β 1- β 2 inter-switch regions of Rab8 via an intermolecular β -sheet (Itzen, Pylypenko et al. 2006). Mss4 induces structural changes in switch I and α 1 of Rab8, disrupting phosphate

and Mg^{2+} binding regions, opening of the nucleotide binding pocket. The Switch II region of Rab8 is not involved in the contact interface, in contrast to other GEF/Rab complexes (Fig 4.3).

In the structure of nucleotide free Rabex-5/Rab21, a helical-bundle Vps9 domain of the Rabex-5 catalytic core binds the switch/inter-switch regions and P-loop of Rab21 inducing an open conformation of the nucleotide binding pocket. Asp185 of Vps9 interacts with the conserved Lys21 from the Rab21 P-loop disrupting the phosphate and Mg^{2+} binding sites and stabilizing the disordered P-loop (Fig 4.3) and the switch II region (Delprato and Lambright 2007).

TRAPP1 is a multimeric membrane tethering complex and acts a GEF for Ypt1 of yeast. In contrast to other GEFs, the catalytic core of TRAPP1 is distributed among multiple subunits: Trs23p, Bet3p and Bet5p. In the crystal structure of TRAPP1/Ypt1, TRAPP1 is seen to interact with the N-terminus, β 1, Switch I, II and P-loop of Ypt1 (Fig 4.3). The C-terminus of Bet3p of TRAPP1 interacts with switch I region opening of the nucleotide binding pocket and disrupting the phosphate and Mg^{2+} binding sites to release GDP (Chin, Cai et al. 2009).

Sec2p functions as a GEF for the Rab GTPase Sec4p in yeast. The crystal structure of nucleotide free Sec2p/Sec4p revealed that Sec2p exhibits a parallel, homodimeric, coiled coil structure. Sec2p interacts with the Switch regions and the P-loop of Sec4p (Dong, Medkova et al. 2007; Sato, Fukai et al. 2007). Upon complex formation, Switch I residues involved in GDP base and sugar moiety binding undergo positional change, where Ile50 of Sec4p is forcibly placed close to the site occupied by Mg^{2+} in the nucleotide-bound forms. In this way, Ile50 disrupts the Mg^{2+} binding site of the P-loop, thus lowering the Sec4p affinity for GDP.

The GEF domain of SidM interacts with β 1, switch I, II and P-loop of Rab1A displacing switch I away from the nucleotide binding site, stabilizing the P-loop and disrupting Mg^{2+} and phosphate binding site (Fig 4.2) releasing GDP from Rab1A.

Comparing the structures of GEF/Rab complexes indicates that Switch I displacement (including conserved residues involved in nucleotide binding) invariably induces nucleotide release. Similarly, all GEFs are seen to disrupt the Mg^{2+} and phosphate binding sites by inserting disruptive residues or by facilitating conformational changes. And finally, Switch II is forced to adopt an ordered conformation by GEFs.

Figure 4.3: Comparison of the Crystal structures of different Rab:GEF Complexes. In the Rab: GEF complex structures, Rab proteins are color coded in green and GEF domains are represented in cyan. The structural elements of Rab GTPases involved in the interaction are color coded as switch I- blue, switch II- red, interswitch region- salmon and P-loop in magenta. Images were drawn by pymol using coordinates of crystal structures with the following PDB codes: 2FU5 (Mss4: Rab8), 2OT3 (Rabex-5: Rab21), 2COY (Sec4: Sec2) and 3CUE (TRAPP: Ypt1).

5 Conclusions and Outlook

In this thesis, full length and six C-terminal truncation variants of human Rab1A were produced to study the interaction with C-terminal domain of SidM (317-545). Each of them was screened over a wide variety of conditions to produce crystals in complex with SidM₃₁₇₋₅₄₅ with the aim of solving the crystal structure of the complex. All truncation variants showed tight interaction with SidM₃₁₇₋₅₄₅. However only the complex consisting of SidM₃₁₇₋₅₄₅ and Rab1A₁₋₁₇₅ and where both genes were co-expressed in *E. coli* was successfully crystallized. This implies that the C-terminus of Rab1A is flexible and hinders the crystallization of the complex.

The interaction between two proteins were analysed by SEC, ITC and X-ray crystallography methods. The crystal structure of the SidM/Rab1A complex was solved, revealing that the GEF domain of SidM is structurally distinct from other known eukaryotic GEFs. The structure of the complex further revealed that SidM interacts mainly

with switch I, switch II and P-loop of Rab1A and induces conformational changes by dislocating switch I away from the nucleotide binding site and thereby disrupting Mg^{2+} and phosphate binding site releasing GDP from Rab1A. This is how SidM acts as an efficient GEF for Rab1A.

Based on the structural information of the complex, SidM interacting residues Glu35, Tyr37 and Ile41 of switch I of Rab1A were substituted by alanine to assess the role of switch I in the binding affinity with SidM. ITC experiments have shown that these variants bind SidM with weaker affinity than wild type Rab1A. These results indicate that Switch I is critical for SidM binding. On the other side, critical Rab1A interacting residues of SidM can also be targeted for mutational and structural analysis. Co-crystallizing these variants in complex and solving their crystal structures would give us detail insight on the mode of interaction between two proteins.

Acknowledgements

I would like to thank my supervisor Prof.Dr. Wolf-Dieter Schubert for his kind support, guidance and giving me the opportunity to work independently in his group. His expertise and commitment were essential to the success of this work, not least by his ever-open ear for questions and discussion. With untiring efforts he has done everything to complete the elaborate move to South Africa and quickly organized and to ensure good conditions in South Africa for successful research at a high level. He also helped us to all problems away from the lab, so bring a move to a new country with him, always a helping hand to the side, and thus has made us feel at home. He helped me and my wife a lot to have a comfortable stay in South Africa. His accommodative nature and encouragement have made my time here a truly comfortable yet enriching learning experience.

I would like to thank Prof. Dirk Heinz for giving me the opportunity to work in his department and the making available of a modern laboratory equipment and infrastructure during the time at HZI. Even after moving to South Africa, we were still actively supported by his department. I thank you also for joining my initial "Thesis Committee," and very helpful suggestions and discussions.

I am very grateful to Prof. Dr. Michael Steinert for joining my thesis committee and being my examiner. I also thank him for accepting my courses to complete my PhD successfully. I also would like to thank Prof. Ralf-Rainer Mendel for the takeover of the Presidency examination.

I would like to thank Dr. Joop van den Heuvel and his team for the regular production of Rab1 protein during my stay at HZI. I am very thankful to Prof. David Pugh and Prof. Trevor Sewell for being my thesis committee members at UWC, South Africa.

I also would like to thank Dr. Mathias Machner for providing us the constructs of Rab and SidM proteins. I would like to thank Christine Holland for her help and training me in the lab during my initial days at HZI. I thank Dr. Manfred Nimtz and team, Rita and Salome Smit Getzlaff for mass spectrometric and N-terminal sequencing.

My special thanks to Nils and Lilia for their kind support and suggestions in the lab. It was very nice working with you. Your friendly nature had made me and my wife feel at home. I always cherish the moments that we spend together in South Africa being like family members.

A big "thank you" goes to Ute Widow, the best TA ever. If we missed a person in Cape Town on the work, then you.

I also thank, Maike Bublitz for her suggestions during my stay at HZI. I also thank Uwe and all the other members of HZI for their nice working environment. I thank Muzi, Donne, Rowan, Clive and all the other members of the lab at UWC, South Africa.

I am very thankful to Dr. Konrad Bussow for spending his valuable time in correcting my thesis. I thank all current and former colleagues in the Structural Biology at the HZI and Biotechnology at UWC in South Africa, I would like to unreservedly thank you for the great working atmosphere, fun lunch breaks and various "After Work" events.

I thank Madhu Nagaraj for his friendly nature and for his cooking skills during my stay in Braunschweig.

This work would not have been possible without the great support of my wife Devi. Devi, I cannot write here, for your kind support and love that you gave me all the time. Thank you, thank you very much. I thank my family members for their kind support. Last but not the least, I thank my almighty GOD for his blessings.

Curriculum Vitae

ADDRESS

Edukondalu Mullapudi
Research Associate
Department of Structural Virology
Central European Institute of Technology (CEITEC)
Kamenice 753/5, Building A35
62500 Brno, Czech Republic
Email: mullapudiedukondalu@gmail.com

Phone: +420702930988

PERSONAL DETAILS

Name	: Edukondalu Mullapudi
Date of Birth	: 03-04-1984
Gender	: Male
Marital	: Married
Nationality	: Indian

EDUCATION

PhD (2009-2014) in Structural Biology, **Helmholtz Centre for Infection Research**, Braunschweig, Germany and **University of the Western Cape**, South Africa

MSc (2007) in Molecular biology, **University of Skövde**, Skövde, Sweden

B.Sc (2005) in Biotechnology, Biochemistry, Chemistry, SPACES Degree College, **Andhra University**, Vishakhapatnam, India

PROFESSIONAL CAREER

Research Associate (August 2013- till date) at Central European Institute of Technology (CEITEC), Brno, Czech Republic

Research Associate (March 2012-Dec 2012) at Institute for Microbial Biotechnology and Metagenomics (IMBM), University of the Western Cape, Cape Town.

Research Expertise

Biochemistry, Molecular Biology, Protein Chemistry, Structural Biology and Microbiology

CONFERENCES

2010 Talk: Structural and functional characterization of the protein SidM of Legionella Pneumophila and its complex with human guanosine triphosphatase Rab1A, awarded prize at **Biotechnology Research Open Day**, University of the Western Cape, Cape Town, South Africa

2008: Attended 3rd **Colloquium DFG Priority Program SPP 1150, Signal Pathways to the cytoskeleton and Bacterial Pathogenesis**, Freiburg, Germany, September 7-9, 2008

2008: Attended **11th Heart of Europe Bio-Crystallography Meeting (HEC 11)**, Greifswald, Germany, September 25 - 27, 2008

CERTIFICATE COURSE

First Aid-Level 2 Training from Department of Labour Approved First Aid Training Organization, SAFENET, South Africa (21-24 June 2010)

Chemical Safety Training from THE SAFETY NETWORK, SAFENET, South Africa (18 June 2010)

Laboratory Safety Training from, THE SAFETY NETWORK, SAFENET, South Africa (15 June 2010)

Standardization of Protocol for PCR based amplification of SY-83 (Sep-Nov 2005), Genetech Professional Education and Training, Hyderabad, India
